

# Practical Cryptography for Blockchains: Minimizing Trust and Maximizing Security

Noemi Glaeser

## Abstract

In 2008, Satoshi Nakamoto introduced Bitcoin, the first digital currency without a trusted authority whose security is maintained by a decentralized blockchain. Since then, a plethora of decentralized applications have been proposed utilizing blockchains as a public bulletin board. This growing popularity has put pressure on the ecosystem to prioritize scalability at the expense of trustlessness and decentralization.

This work explores the role cryptography has to play in the blockchain ecosystem to improve performance while maintaining minimal trust and strong security guarantees. I discuss a new paradigm for scalability, called *naysayer proofs*, which sits between optimistic and zero-knowledge approaches. Next, I show how to construct efficient, non-interactive, and fair on-chain protocols for a large class of elections and auctions without a trusted third party. Finally, I introduce a new type of threshold wallet which adds offline components at each custodian to improve security while maintaining distributed trust. Furthermore, the construction enables transparency by allowing the wallet owner to request custodians to prove “remembrance” of the secret key material. All three of these works will be deployed in practice or have seen interest from practitioners in applying them. These examples show that advanced cryptography has the potential to meaningfully nudge the blockchain ecosystem towards increased security and reduced trust.

# 1 Introduction

Bitcoin [Nak08] was the first digital currency to successfully implement a fully trustless and decentralized payment system. Underpinning Bitcoin is a *blockchain*, a distributed append-only ledger to record transactions. In Bitcoin, the blockchain’s consistency is enforced via a “proof-of-work” (PoW) consensus mechanism in which participants solve difficult computational puzzles (hash preimages) to append the newest bundle of transactions (a block) to the chain.

Ethereum [But14] introduced programmability via *smart contracts*, special applications which sit on top of the consensus layer and can maintain state and modify it programmatically. This has led to the emergence of a number of *decentralized applications* enabling more diverse functionalities.

Unfortunately, as the number of applications and their users has increased, developers have been forced to sacrifice trustlessness and sometimes even security or privacy in favor of performance and scalability. This dissertation uses cryptographic tools to enable blockchain applications which are both *practical* and *secure* while staying true to the original blockchain ethos and minimizing trust. All the works discussed were created in collaboration with industry practitioners and have seen interest or deployment in the blockchain ecosystem.

In Section 2, I introduce the necessary background and building blocks used throughout this dissertation. Section 3 describes *naysayer proofs*, a new paradigm for verifying zero-knowledge proofs in the so-called optimistic setting. One notable application of naysayer proofs is for scalability, where it sits between the existing solutions—optimistic rollups and zero-knowledge rollups—and can provide better performance and accessibility for certain parties in rollup ecosystems. Since their publication, naysayer proofs have seen interest in production deployment from at least two startups (that I am aware of) in the blockchain space.

In Section 4, we move to on-chain applications and describe Cicada, a smart contract protocol for realizing the first *fair* and *non-interactive* on-chain elections and auctions. This resolves important security and usability hurdles in existing systems, which are widely used for on-chain governance votes or sales of digital goods such as non-fungible tokens (NFTs). Cicada is accompanied by a Solidity smart contract implementation, making it easily deployable on Ethereum and a large number of “layer 2” (L2) chains. Furthermore, we have been in contact with Optimism, one of the largest L2s in the ecosystem, to discuss the use of Cicada for their retroPGF funding vote.<sup>1</sup>

Finally, Section 5 moves off-chain and looks at securing the edges of the system: cryptocurrency wallets. We propose a new architecture which aims to boost the security of threshold wallets while maintaining their usability benefits, and present constructions for two popular signature schemes. This design was created with collaborators from Lit Protocol<sup>2</sup> and the Linux Foundation. An Apache 2.0-licensed is also publicly available in Hyperledger Labs<sup>3</sup>, a popular

<sup>1</sup><https://community.optimism.io/docs/governance/>

<sup>2</sup><https://www.litprotocol.com/>

<sup>3</sup><https://github.com/hyperledger-labs>

open source organization.

We conclude in Section 6 by discussing potential future directions for these three works and a broader outlook on the role of cryptography in blockchains.

## 2 Preliminaries

We use  $[n]$  to denote the range  $\{1, \dots, n\}$ . For other ranges (mostly zero-indexed), we explicitly write the (inclusive) endpoints, e.g.,  $[0, n]$ . Concatenation of vectors  $\mathbf{x}, \mathbf{y}$  is written as  $\mathbf{x} \parallel \mathbf{y}$ . Let  $\lambda$  be the security parameter. We use the uppercase variable  $X$  for the free variable of a polynomial, e.g.,  $f(X)$ . We use a calligraphic font, e.g.,  $\mathcal{S}$  or  $\mathcal{X}$ , to denote sets or domains. When we apply an operation to two sets of equal size  $\ell$  we mean pairwise application, e.g.,  $\mathcal{Z} = \mathcal{X} + \mathcal{Y}$  means  $z_i = x_i + y_i \forall i \in [\ell]$ . Sampling an element  $x$  uniformly at random from a set  $\mathcal{X}$  is written as  $x \xleftarrow{\$} \mathcal{X}$ . We use  $:=$  to denote variable assignment,  $y \leftarrow \text{Alg}(x)$  to assign to  $y$  the output of some algorithm  $\text{Alg}$  on input  $x$ , and  $y \xleftarrow{\$} \text{Alg}(x)$  if the algorithm is randomized. When we wish to be explicit about the randomness  $r$  used, we write  $y \leftarrow \text{Alg}(x; r)$ . We use  $\mathcal{D}_1 \approx_\lambda \mathcal{D}_2$  to denote that two distributions  $\mathcal{D}_1, \mathcal{D}_2$  have statistical distance bounded by  $\text{negl}(\lambda)$ .

For a non-interactive proof system  $\Pi$ , we write  $\pi \leftarrow \Pi.\text{Prove}(x; w)$  to show that the proving algorithm takes as input an instance  $x$  and witness  $w$  and outputs a proof  $\pi$ . Verification is written as  $\Pi.\text{Vrfy}(x, \pi)$  and outputs a bit  $b$ .

We distinguish the key-pairs used in a signature scheme ( $\text{vk}, \text{sk}$  for “verification” and “signing” key, respectively) from those used in an encryption scheme ( $\text{ek}, \text{dk}$  for “encryption” and “decryption” key, respectively).

### 2.1 Non-interactive proof systems

**Definition 1** (Non-interactive proof). *A non-interactive proof  $\Pi$  for some NP relation  $\mathcal{R}$  is a tuple of PPT algorithms  $(\text{Setup}, \text{Prove}, \text{Vrfy})$ :*

$\text{Setup}(1^\lambda) \rightarrow \text{crs}$ : *Given a security parameter, output a common reference string crs. This algorithm might use private randomness (a trusted setup).*

$\text{Prove}(\text{crs}, x, w) \rightarrow \pi$ : *Given the crs, an instance  $x$ , and witness  $w$  such that  $(x, w) \in \mathcal{R}$ , output a proof  $\pi$ .*

$\text{Vrfy}(\text{crs}, x, \pi) \rightarrow \{0, 1\}$ : *Given the crs and a proof  $\pi$  for the instance  $x$ , output a bit indicating accept or reject.*

We refer the reader to [Tha23] for a formal description of the properties of proof systems (e.g., correctness, soundness, zero-knowledge).

### 2.2 Time-Lock Puzzles

A time-lock puzzle (TLP) [RSW96] consists of three efficient algorithms  $\text{TLP} = (\text{Setup}, \text{Gen}, \text{Solve})$  allowing a party to “encrypt” a message to the future. To

recover the solution, one needs to perform a computation that is believed to be inherently sequential, with a parameterizable number of steps.

**Definition 2** (Time-lock puzzle [RSW96]). *A time-lock puzzle scheme TLP for solution space  $\mathcal{X}$  consists of the following three efficient algorithms:*

$\text{TLP.Setup}(1^\lambda, T) \xrightarrow{\S} \text{pp}$ . *The (potentially trusted) setup algorithm takes as input a security parameter  $1^\lambda$  and a difficulty (time) parameter  $T$ , and outputs public parameters  $\text{pp}$ .*

$\text{TLP.Gen}(\text{pp}, s) \xrightarrow{\S} Z$ . *Given a solution  $s \in \mathcal{X}$ , the puzzle generation algorithm efficiently computes a time-lock puzzle  $Z$ .*

$\text{TLP.Solve}(\text{pp}, Z) \rightarrow s$ . *Given a TLP  $Z$ , the puzzle-solving algorithm requires at least  $T$  sequential steps to output the solution  $s$ .*

Informally, we say that a TLP scheme is *correct* if  $\text{TLP.Gen}$  is efficiently computable, and  $\text{TLP.Solve}$  always recovers the original solution  $s$  to a validly constructed puzzle. A TLP scheme is *secure* if  $Z$  hides the solution  $s$  and no adversary can compute  $\text{TLP.Solve}$  in fewer than  $T$  steps with non-negligible probability. For the formal definitions, see [MT19].

**Homomorphic TLPs.** Malavolta and Thyagarajan [MT19] introduce *homomorphic* TLPs (HTLPs). An HTLP is defined with respect to a circuit class  $\mathcal{C}$  and has an additional algorithm  $\text{Eval}$  defined as:

$\text{HTLP.Eval}(\text{pp}, C, Z_1, \dots, Z_m) \rightarrow Z_*$ . *Given the public parameters, a circuit  $C \in \mathcal{C}$  where  $C : \mathcal{X}^m \rightarrow \mathcal{X}$ , and input puzzles  $Z_1, \dots, Z_m$ , the homomorphic evaluation algorithm outputs a puzzle  $Z_*$ .*

Correctness requires that  $\text{HTLP.Solve}(Z_*)$  should contain the expected solution, namely  $C(s_1, \dots, s_m)$ , where  $s_i \leftarrow \text{HTLP.Solve}(Z_i)$ . Again, we refer the reader to [MT19] for the formal definition. Moving forward, we will use  $\boxplus$  for homomorphic addition and  $\cdot$  for scalar multiplication of HTLPs. For the homomorphic application of a linear function  $f$ , we write  $f(Z_1, \dots, Z_m)$ .

## 2.3 HTLP Constructions

Malavolta and Thyagarajan [MT19] give two HTLP constructions with linear and multiplicative homomorphisms, respectively. They require  $N$  to be a *strong* semiprime, i.e.,  $N = p \cdot q$  such that  $p = 2p' + 1$  and  $q = 2q' + 1$  where  $p', q'$  are also prime. The linearly-homomorphic HTLP is based on Paillier encryption [?], while the multiplicative homomorphism is achieved by working over the subgroup  $\mathbb{J}_N \subseteq \mathbb{Z}_N^*$  of elements with Jacobi symbol  $+1$ . We recall their constructions in Figure 1.

Correctness of the linear HTLP holds because for all  $s \in \mathbb{Z}_N$  and  $Z = (u, v) \leftarrow \text{HTLP.Gen}(\text{pp}, s)$ ,

$$\text{HTLP.Open}(\text{pp}, Z) = \frac{(v/(h^R)^N \bmod N^2) - 1}{N} = \frac{((1+N)^s) - 1}{N} = s \quad (1)$$

since  $(1 + N)^x = 1 + Nx \pmod{N^2}$ . Correctness of the homomorphism follows since for all linear functions  $f(x_1, x_2) = b + a_1x_1 + a_2x_2$  and all  $Z_i = (u_i, v_i) \in \text{Im}(\text{HTLP.Gen}(\text{pp}, s_i; r_i))$  for  $i \in \{1, 2\}$ ,<sup>4</sup>

$$\begin{aligned} \text{HTLP.Eval}(\text{pp}, f, Z_1, Z_2) &= (u_1^{a_1} \cdot u_2^{a_2}, (1 + N)^b \cdot v_1^{a_1} \cdot v_2^{a_2}) \\ &= (g^{r_1 a_1} \cdot g^{r_2 a_2}, (1 + N)^b \cdot h^{r_1 N a_1} \cdot (1 + N)^{s_1 a_1} \cdot h^{r_2 N a_2} \cdot (1 + N)^{s_2 a_2}) \\ &= (g^{r_1 a_1 + r_2 a_2}, h^{(r_1 a_1 + r_2 a_2) \cdot N} \cdot (1 + N)^{b + s_1 a_1 + s_2 a_2}) \\ &= \text{HTLP.Gen}(\text{pp}, f(s_1, s_2); r_1 a_1 + r_2 a_2) \end{aligned}$$

which opens to  $f(s_1, s_2)$  by eq. (1).

The multiplicative HTLP operates over the solution space  $\mathbb{J}_N$  (instead of  $\mathbb{Z}_N$ ). It is easy to see that  $\text{HTLP.Open}(\text{pp}, \text{HTLP.Gen}(\text{pp}, s)) = s$  for all  $s \in \mathbb{Z}_N^*$ . Furthermore, for all  $f(x_1, x_2) = ax_1x_2$  and all  $Z_i = (u_i, v_i) \in \text{Im}(\text{HTLP.Gen}(\text{pp}, s_i; r_i))$  for  $i \in \{1, 2\}$ ,

$$\begin{aligned} \text{HTLP.Eval}(\text{pp}, f, Z_1, Z_2) &= (u_1 \cdot u_2 \pmod{N}, a \cdot v_1 \cdot v_2 \pmod{N}) \\ &= (g^{r_1} g^{r_2} \pmod{N}, h^{r_1} h^{r_2} \cdot a s_1 s_2 \pmod{N}) \\ &= (g^{r_1 + r_2} \pmod{N}, h^{r_1 + r_2} \cdot a s_1 s_2 \pmod{N}) \\ &= \text{HTLP.Gen}(\text{pp}, f(s_1, s_2); r_1 + r_2) \end{aligned}$$

Thus correctness holds.

## 2.4 Vector Packing

**Definition 3** (Vector packing). *A setup algorithm PSetup and pair of efficiently computable bijective functions (Pack, Unpack) is called a packing scheme and has the following syntax:*

- $\text{PSetup}(\ell, w) \rightarrow \text{pp}$ . Given a vector dimension  $\ell$  and maximum entry  $w$ , output public parameters  $\text{pp}$ .
- $\text{Pack}(\text{pp}, \mathbf{a}) \rightarrow s$ . Encode  $\mathbf{a} \in (\mathbb{Z}^+)^{\ell}$  as a positive integer  $s \in \mathbb{Z}^+$ .
- $\text{Unpack}(\text{pp}, s) \rightarrow \mathbf{a}$ . Given  $s \in \mathbb{Z}^+$ , recover a vector  $\mathbf{a} \in (\mathbb{Z}^+)^{\ell}$ .

For correctness we require  $\text{Unpack}(\text{Pack}(\mathbf{a})) = \mathbf{a}$  for all  $\mathbf{a} \in (\mathbb{Z}^+)^{\ell}$ .

The classic approach to packing [Gro05, HS00] uses a *positional numeral system (PNS)* to encode a vector of entries bounded by  $w$  as a single integer in base  $M := w$  (see Construction 3 below). Instead, we will set  $M := nw + 1$  to accommodate the homomorphic addition of all  $n$  users' vectors: each voter submits a length- $m$  vector with entries  $\leq w$ . Summing over  $n$  voters, the result is a length- $m$  vector with a maximum entry value  $nw$ ; to prevent overflow, we set  $M = nw + 1$ .

<sup>4</sup>For space and clarity we drop the moduli and assume that we are working in the appropriate ring in each coordinate (namely  $\mathbb{Z}_N$  and  $\mathbb{Z}_{N^2}$ , respectively).

**Construction 3** (Packing from Positional Numeral System).

- $\text{PSetup}(\ell, w) \rightarrow M$  : Return  $M := w + 1$ .
- $\text{Pack}(M, \mathbf{a}) \rightarrow s$  : Output  $s := \sum_{j=1}^{|\mathbf{a}|} a_j M^{j-1}$ .
- $\text{Unpack}(M, s) \rightarrow \mathbf{a}$  : Let  $\ell := \lceil \log_M s \rceil$ . For  $j \in [\ell]$ , compute the  $j$ th entry of  $\mathbf{a}$  as  $a_j := s \bmod M^j$ .

Besides PNS packing, we also introduce an alternative approach in Construction 4 which is based on the *residue numeral system (RNS)*. The idea of the RNS packing is to interpret the entries of  $\mathbf{a}$  as prime residues of a single unique integer  $s$ , which can be found efficiently using the Chinese Remainder Theorem (CRT). In other words, for all  $j \in [\ell]$ ,  $s$  captures  $a_j$  as  $s \bmod p_j$ .

**Construction 4** (Packing from Residue Numeral System).

- $\text{PSetup}(\ell, w) \rightarrow \mathbf{p}$  : Let  $M := w + 1$  and sample  $\ell$  distinct primes  $p_1, \dots, p_\ell$  s.t.  $p_j \geq M \ \forall j \in [\ell]$ . Return  $\mathbf{p} := (p_1, \dots, p_\ell)$ .
- $\text{Pack}(\mathbf{p}, \mathbf{a}) \rightarrow s$  : Given  $\mathbf{a} \in (\mathbb{Z}^+)^{\ell}$ , use the CRT to find the unique  $s \in \mathbb{Z}^+$  s.t.  $s \equiv a_j \pmod{p_j} \ \forall j \in [\ell]$ .
- $\text{Unpack}(\mathbf{p}, s) \rightarrow \mathbf{a}$  : return  $(a_1, \dots, a_\ell)$  where  $a_j \equiv s \bmod p_j \ \forall j \in [\ell]$ .

A major advantage of this approach is that, in contrast to the PNS approach, which is only homomorphic for SIMD (single instruction, multiple data) addition, the RNS encoding is fully SIMD homomorphic: the sum of vector encodings  $\sum_{i \in [n]} s_i$  encodes the vector  $\mathbf{a}_+ = \sum_{i \in [n]} \mathbf{a}_i$ , and the product  $\prod_{i \in [n]} s_i$  encodes the vector  $\mathbf{a}_\times = \prod_{i \in [n]} \mathbf{a}_i$ .

## 2.5 Bilinear Pairings

**Definition 4** (bilinear pairing). A bilinear pairing is a map  $e : \mathbb{G}_1 \times \mathbb{G}_2 \mapsto \mathbb{G}_T$  where  $\mathbb{G}_1, \mathbb{G}_2$ , and  $\mathbb{G}_T$  are cyclic groups of prime order  $p$ . (Often,  $\mathbb{G}_1, \mathbb{G}_2$  are written in additive notation and  $\mathbb{G}_T$  in multiplicative notation.) Let  $g_1, h_1 \in \mathbb{G}_1$  and  $g_2, h_2 \in \mathbb{G}_2$  (generators of their respective groups). The map  $e$  has the following properties:

**Bilinearity:** For all  $a, b \in \mathbb{Z}_p^*$ , the following hold:

$$\begin{aligned} e(g_1^a, g_2) &= e(g_1, g_2^a) = e(g_1, g_2)^a \\ e(g_1 h_1, g_2) &= e(g_1, g_2) \cdot e(h_1, g_2) \\ e(g_1, g_2 h_2) &= e(g_1, g_2) \cdot e(g_1, h_2) \end{aligned}$$

**Non-degeneracy:**  $e(g_1, g_2) \neq 1$ .

**Computability:** There is an efficient algorithm for computing  $e$ .

Pairings are divided into types based on the (in)equality of the utilized groups  $\mathbb{G}_1, \mathbb{G}_2$  and whether there is an efficiently computable homomorphism between the groups. For our purposes, we will use a type-3 pairing: asymmetric ( $\mathbb{G}_1 \neq \mathbb{G}_2$ ) and with no such efficiently computable homomorphism. In this case, the Decisional Diffie-Hellman (DDH) assumption is believed to hold in both  $\mathbb{G}_1$  and  $\mathbb{G}_2$ ; this is referred to as the *symmetric external Diffie-Hellman (SXDH) assumption*.

## 2.6 Shamir Secret Sharing

Shamir [Sha79] introduced a scheme to share a secret among  $n$  parties such that any  $t$  parties can work together to recover the secret, but with any fewer parties the secret remains information-theoretically hidden.

**Construction 5** (Shamir secret sharing [Sha79]). *Let  $p$  be a prime.*

- $\{s_1, \dots, s_n\} \leftarrow \text{Share}(s, t, n)$ : *Given a secret  $s \in \mathbb{Z}_p$  and  $t \leq n \in \mathbb{N}$ , compute a  $t$ -out-of- $n$  sharing of  $s$  by choosing a random degree- $(t-1)$  polynomial  $f(X) \in \mathbb{Z}_p[X]$  such that  $f(0) = s$ . For  $i \in [n]$ , compute  $s_i := (i, f(i))$ .*
- $\{s', \perp\} \leftarrow \text{Reconstruct}(S, t, n)$ : *Given some set of shares  $S$ , check if  $|S| < t$ . If so, output  $\perp$ . Otherwise, without loss of generality, let  $S' := \{s_1, \dots, s_t\}$  be the first  $t$  entries of  $S$ , where  $s_i := (x_i, y_i)$ . Output the Lagrange interpolation at 0:*

$$s' := \sum_{i=1}^t y_i \prod_{j=1, j \neq i}^t \frac{x_j}{x_j - x_i}.$$

The secret sharing scheme is *correct*, since for any secret  $s$  and values  $t \leq n \in \mathbb{N}$ , we have  $\text{Reconstruct}(\text{Share}(s, t, n), t, n) = s$ .

For notational convenience, let  $\text{Share}(s, t, n; r)[i]$  denote the  $i$ th share of  $s$  computed with randomness  $r$ . The reconstruction algorithm can be generalized to interpolate any point  $f(k)$  (not just the secret at  $k = 0$ ) and thereby recover the  $i$ th share:

- $\{s_k, \perp\} \leftarrow \text{Interpolate}(S, k, t, n)$ : *If  $|S| < t$ , output  $\perp$ . Otherwise, use the first  $t$  entries  $(x_1, y_1), \dots, (x_t, y_t)$  of  $S$  to interpolate*

$$f(k) = \sum_{i=1}^t y_i \prod_{j=1, j \neq i}^t \frac{x_j - k}{x_j - x_i}.$$

Output  $s_k := (k, f(k))$ .

## 2.7 Digital Signatures

A *digital signature* **todo: [?]** is a cryptographic primitive which **todo: ...**

### 2.7.1 BLS Signatures

**Construction 6** (BLS signature scheme [BLS01]). Let  $\mathbb{G}_1, \mathbb{G}_2$  be elliptic curve groups of order  $p$  generated by  $g_1$  and  $g_2$ , respectively, and  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  be an efficiently computable asymmetric pairing between them. We also require a hash function  $H : \{0, 1\}^* \rightarrow \mathbb{G}_1$ . The signature scheme works as follows:

- $(\text{sk}, \text{vk}) \leftarrow \text{KGen}(1^\lambda)$ : Given the security parameter  $1^\lambda$ , sample  $x \xleftarrow{\$} \mathbb{Z}_p$  and output the keypair consisting of signing key  $\text{sk} := x$  and verification key  $\text{vk} := g_2^x$ .
- $\sigma \leftarrow \text{Sign}(\text{sk}, m)$ : Given a signing key  $\text{sk} \in \mathbb{Z}_p$  and a message  $m \in \{0, 1\}^*$ , compute a signature  $\sigma := H(m)^{\text{sk}}$ .
- $\{0, 1\} \leftarrow \text{Vrfy}(\text{vk}, m, \sigma)$ : Given a verification key  $\text{vk} \in \mathbb{G}_2$ , message  $m \in \{0, 1\}^*$ , and signature  $\sigma \in \mathbb{G}_1$ , if  $e(\sigma, g_2) = e(H(m), \text{vk})$ , output 1. Else output 0.

The security of BLS relies on the gap co-Diffie Hellman assumption on  $(\mathbb{G}_1, \mathbb{G}_2)$ , i.e., co-DDH being easy but co-CDH being hard on  $\mathbb{G}_1, \mathbb{G}_2$ , as well as the existence of an efficiently computable homomorphism  $\phi : \mathbb{G}_2 \rightarrow \mathbb{G}_1$  (type-2 pairing). Since we require a type-3 pairing for our purposes (i.e., no efficiently computable  $\phi$  exists), we rely on a stronger variant of the co-GDH assumption (see discussion in [BLS01, §3.1] and [SV05, §2.2]).

**Threshold variant** Sharing a BLS signing key  $\text{sk} \in \mathbb{Z}_p$  via Shamir secret sharing leads directly to a robust  $t$ -out-of- $n$  threshold signature [BLS01]. More specifically, each party  $i \in [n]$  receives a  $t$ -out-of- $n$  Shamir secret share  $\text{sk}_i$  of the key. The “partial” public keys  $\text{vk}_i := g_2^{\text{sk}_i}$  are published along with the public key  $\text{vk}$ .

A partial signature is computed in exactly the same way as a regular BLS signature, but under the secret key share:  $\sigma_i := H(m)^{\text{sk}_i}$ . This value is publicly verifiable by checking that  $(g_2, \text{vk}_i, H(m), \sigma_i)$  is a co-Diffie-Hellman tuple (i.e., it is of the form  $(g_2, g_2^a, h, h^a)$  where  $g_2 \in \mathbb{G}_2$  and  $h \in \mathbb{G}_1$ ).

Given  $t$  valid partial signatures on a message  $m \in \{0, 1\}^*$  anyone can recover a regular BLS signature:

- $\sigma \leftarrow \text{Reconstruct}(S := \{(i, \sigma_i)\})$ : Let  $S' \subseteq S$  be the set of valid partial signatures in  $S$ . If  $|S'| < t$ , output  $\perp$ . Otherwise, without loss of generality, assume the first  $t$  valid signatures come from users  $1, \dots, t$  and recover the complete signature as

$$\sigma \leftarrow \prod_{i=1}^t \sigma_i^{\lambda_i}, \text{ where } \lambda_i = \prod_{j=1, j \neq i}^t \frac{j}{j-i} \pmod{p}$$

Notice that the reconstruction simply performs Shamir reconstruction of the signing key shares  $\text{sk}_i$  in the exponent and thus the output will equal  $H(m)^{\text{sk}}$ .

Hence, the complete signature is indistinguishable from a regular BLS signature, and verification proceeds exactly as in the regular scheme.

subsubsectionSchnorr Signatures

**Definition 5** (Schnorr signature [Sch90]). *Let  $\text{pp} = (\mathbb{G}, g, q)$  be description of a cyclic group  $\mathbb{G}$  of prime order  $q$  with generator  $g$  in which the discrete logarithm problem is hard.*

$\text{KGen}(\text{pp}) \rightarrow (\text{sk}, \text{vk})$ . *Sample a secret key  $\text{sk} \xleftarrow{\$} \mathbb{Z}_q$  and set the corresponding verification key  $\text{vk} := g^{\text{sk}} \in \mathbb{G}$ . Output  $(\text{sk}, \text{vk})$ .*

$\text{Sign}(\text{sk}, m) \rightarrow \sigma$ . *Given a secret key  $\text{sk} \in \mathbb{Z}_q$  and message  $m$ , sample  $k \xleftarrow{\$} \mathbb{Z}_q$  and let  $R := g^k$ . Compute  $c := H(m, g^{\text{sk}}, R)$  and  $s := k + c \cdot \text{sk}$ . Output  $\sigma := (R, s)$ .*

$\text{Vrfy}(\text{vk}, m, \sigma) \rightarrow \{0, 1\}$ . *Given a verification key  $\text{vk}$ , message  $m$ , and signature  $\sigma$ , compute  $c := H(m, \text{vk}, R)$  and check  $R \cdot \text{vk}^c \stackrel{?}{=} s$ . If so, output 1, else 0.*

Noemi: Schnorr (threshold) signatures; [Lin22] and [KG20] use different definitions of Schnorr, are they equivalent?

**Threshold variants** Many protocols exist for threshold Schnorr signatures **todo**: [?], each offering a different combination of properties. **todo**: ...

The BLS threshold signature scheme [BLS01] is fully non-interactive, meaning that signing occurs in one round. FROST is a “somewhat” non-interactive threshold signature scheme [BTZ22] in the sense that the *signing* procedure consists of a single round, but there is another round of message-independent pre-processing.

## 2.8 KZG polynomial commitments

KZG commitments can be instantiated using either a symmetric or asymmetric pairing; we give the asymmetric version of KZG below.

**Construction 7** (KZG polynomial commitments [KZG10]). *Let  $\mathbb{G}_1, \mathbb{G}_2$  be elliptic curve groups of order  $p$  with generators  $g_1, g_2$  and  $e : \mathbb{G}_1 \times \mathbb{G}_2 \mapsto \mathbb{G}_T$  be an elliptic curve pairing. The following is a commitment scheme for polynomials in  $\mathbb{Z}_p[X]$  with degree at most  $d$ .*

- $\text{crs} \leftarrow \text{Setup}(d)$  : *Sample  $\tau \xleftarrow{\$} \mathbb{Z}_p$  and output  $\text{crs} := \{g_1, g_1^\tau, g_1^{\tau^2}, \dots, g_1^{\tau^d}, g_2, g_2^\tau\}$ .*
- $\text{com}_f \leftarrow \text{Com}(\text{crs}, f(X))$  : *Let  $f(X) = a_0 + a_1X + \dots + a_dX^d \in \mathbb{Z}_p[X]$ . Use  $\text{crs}$  to compute and output  $g_1^{f(\tau)} = g_1^{a_0} \cdot (g_1^\tau)^{a_1} \dots (g_1^{\tau^d})^{a_d} = g_1^{a_0 + a_1\tau + \dots + a_d\tau^d} \in \mathbb{G}_1$ .*

- $(f(i), \pi_i) \leftarrow \text{Open}(\text{crs}, f(X), i)$  : To open  $f(X)$  at  $i$ , let  $q_i(X) := \frac{f(X) - f(i)}{X - i} \in \mathbb{Z}_p[X]$ <sup>5</sup>. Then compute  $\text{com}_{q_i} \leftarrow \text{Com}(\text{crs}, q_i(X))$  and output  $(f(i), \text{com}_{q_i}) \in \mathbb{Z}_p \times \mathbb{G}_1$ .
- $\{0, 1\} \leftarrow \text{Vrfy}(\text{crs}, \text{com}_f, i, y, \pi_i)$  : To confirm  $y = f(i)$ , it suffices to check that  $q_i(X) = \frac{f(X) - y}{X - i}$  at  $X = \tau$ . This can be done with a single pairing check:

$$e(\text{com}_f / g_1^y, g_2) \stackrel{?}{=} e(\pi_i, g_2^\tau / g_2^i)$$

The security of the scheme relies on the  $d$ -Strong Diffie Hellman assumption ( $d$ -SDH), which states that given  $\{g_1, g_1^\tau, \dots, g_1^{\tau^d}, g_2, g_2^\tau\}$ , it is difficult to compute  $(c, g_1^{\frac{1}{\tau - c}})$  for any  $c \in \mathbb{Z}_p \setminus \{-\tau\}$ . This assumption is stronger than  $d$ -SDH in  $\mathbb{G}_1$ , which in turn implies DDH in  $\mathbb{G}_1$ .

## 2.9 Pedersen Commitments

Next, we recall Pedersen commitments [Ped92], a commitment scheme which is unconditionally (information-theoretically) hiding and computationally binding (by the discrete logarithm assumption on  $\mathbb{G}$ ). In our construction we will instantiate the scheme over  $\mathbb{G}_1$ , so we let  $\mathbb{G} = \mathbb{G}_1$  in the description below.

**Construction 8** (Pedersen commitment scheme [Ped92]). *Let  $\mathbb{G}_1$  be a group of order  $p$  and  $g_1, h_1$  be generators of  $\mathbb{G}_1$ . The following is a commitment scheme for elements  $x \in \mathbb{Z}_p$ .*

- $(\text{com}, \text{decom}) \leftarrow \text{Com}(x)$  : Sample  $r \xleftarrow{\$} \mathbb{Z}_p$  and return  $\text{com} := g_1^x h_1^r$  and decommitment information  $(x, r)$ .
- $(x, r) \leftarrow \text{Open}(\text{com}, \text{decom})$  : To open  $\text{com}$ , directly output  $\text{decom} = (x, r)$ .
- $\{0, 1\} \leftarrow \text{Vrfy}(\text{com}, x, r)$  : To confirm the opening of  $\text{com}$  to  $x$ , it suffices to check that  $\text{com} = g_1^x h_1^r$ .

A PoK of the committed value can be computed using a Sigma protocol due to Okamoto [Oka93], which can be made non-interactive using the Fiat-Shamir transform [FS87]. We refer to this protocol as  $\Pi_{\text{ped}}$  and present it in Figure 2.

## 2.10 Leftover Hash Lemma

We use the presentation of the leftover hash lemma (LHL) [IZ89] from [AMPR19].<sup>6</sup> Let  $(\mathcal{X}, \oplus)$  be a finite group of size  $|\mathcal{X}|$ , and let  $n$  be a positive integer. For any fixed  $2n$ -vector of group elements  $\mathbf{x} = \{x_{j,b}\}_{j \in [n], b \in \{0,1\}} \in \mathcal{X}^{2n}$ , denote by  $\mathcal{S}_{\mathbf{x}}$  the following distribution:

$$\mathcal{S}_{\mathbf{x}} = \left\{ \bigoplus_{j \in [n]} x_{j, r_j} : (r_1, \dots, r_n) \leftarrow \{0, 1\}^n \right\}.$$

<sup>5</sup>This is a polynomial by Little Bézout's Theorem.

<sup>6</sup>We specifically use the improved version from the Journal of Cryptology version of this paper.

Also, let  $\mathcal{U}_{\mathcal{X}}$  denote the uniform distribution over  $\mathcal{X}$ , and let  $\Delta(\mathcal{D}_1, \mathcal{D}_2)$  denote the statistical distance between the distributions  $\mathcal{D}_1$  and  $\mathcal{D}_2$ . We will use the following special case of leftover hash lemma [IZ89]. The proof can be found in the JoC version of [AMPR19].

**Lemma 1.** (Leftover Hash Lemma.) *Let  $(\mathcal{X}, \oplus)$  be a finite group, and let  $\mathcal{S}_{\mathbf{x}}$  and  $\mathcal{U}_{\mathcal{X}}$  be two distributions over  $\mathcal{X}$  as defined above. For any (large enough) positive integer  $n$ , it holds that*

$$\Pr_{\mathbf{x} \leftarrow \mathcal{X}^{2n}} \left[ \Delta(\mathcal{S}_{\mathbf{x}}, \mathcal{U}_{\mathcal{X}}) > \sqrt[4]{\frac{|\mathcal{X}|}{2^n}} \right] \leq \sqrt[4]{\frac{|\mathcal{X}|}{2^n}}.$$

*In particular, for any  $n > \log(|\mathcal{X}|) + \omega(\log(\lambda))$ , if  $\mathbf{x}$  is sampled uniformly then with overwhelming probability the statistical distance between two distributions is negligible.*

## 2.11 Universal Composability (UC) Framework

In the universal composability (UC) framework [Can01], the security requirements of a protocol are defined via an *ideal functionality* which is executed by a trusted party. To prove that a protocol *UC-realizes* a given ideal functionality, we show that the execution of this protocol (in the real or hybrid world) can be *emulated* in the ideal world, where in both worlds there is an additional adversary  $\mathcal{E}$  (the environment) which models arbitrary concurrent protocol executions. Specifically, we show that for any adversary  $\mathcal{A}$  attacking the protocol execution in the real world (by controlling communication channels and corrupting parties involved in the protocol execution), there exists an adversary  $\mathcal{S}$  (the simulator) in the ideal world who can produce a protocol execution which no environment  $\mathcal{E}$  can distinguish from the real-world execution.

Below we describe the UC framework as it is presented in [CLOS02]. All parties are represented as probabilistic interactive Turing machines (ITMs) with input, output, and ingoing/outgoing communication tapes. For simplicity, we assume that all communication is authenticated, so an adversary can only delay but not forge or modify messages from parties involved in the protocol. Therefore, the order of message delivery is also not guaranteed (asynchronous communication). We consider a PPT malicious, adaptive adversary who can corrupt or tamper with parties at any point during the protocol execution.

The execution in both worlds consists of a series of sequential party activations. Only one party can be activated at a time (by writing a message on its input tape). In the real world, the execution of a protocol  $\Pi$  occurs among parties  $P_1, \dots, P_n$  with adversary  $\mathcal{A}$  and environment  $\mathcal{E}$ . In the ideal world, interaction takes place between dummy parties  $\tilde{P}_1, \dots, \tilde{P}_n$  communicating with the ideal functionality  $\mathcal{F}$ , with the adversary (simulator)  $\mathcal{S}$  and environment  $\mathcal{E}$ . Every copy of  $\mathcal{F}$  is identified by a unique session identifier `sid`.

In both the real and ideal worlds, the environment is activated first and activates either the adversary ( $\mathcal{A}$  resp.  $\mathcal{S}$ ) or an uncorrupted (dummy) party by

writing on its input tape. If  $\mathcal{A}$  (resp.  $\mathcal{S}$ ) is activated, it can take an action or return control to  $\mathcal{E}$ . After a (dummy) party (or  $\mathcal{F}$ ) is activated, control returns to  $\mathcal{E}$ . The protocol execution ends when  $\mathcal{E}$  completes an activation without writing on the input tape of another party.

We denote with  $\text{REAL}_{\Pi, \mathcal{A}, \mathcal{E}}(\lambda, x)$  the random variable describing the output of the real-world execution of  $\Pi$  with security parameter  $\lambda$  and input  $x$  in the presence of adversary  $\mathcal{A}$  and environment  $\mathcal{E}$ . We write the corresponding distribution ensemble as  $\{\text{REAL}_{\Pi, \mathcal{A}, \mathcal{E}}(\lambda, x)\}_{\lambda \in \mathbb{N}, x \in \{0,1\}^*}$ . The output of the ideal-world interaction with ideal functionality  $\mathcal{F}$ , adversary (simulator)  $\mathcal{S}$ , and environment  $\mathcal{E}$  is represented by the random variable  $\text{IDEAL}_{\mathcal{F}, \mathcal{S}, \mathcal{E}}(\lambda, x)$  and corresponding distribution ensemble  $\{\text{IDEAL}_{\mathcal{F}, \mathcal{S}, \mathcal{E}}(\lambda, x)\}_{\lambda \in \mathbb{N}, x \in \{0,1\}^*}$ .

The actions each party can take are summarized below:

- Environment  $\mathcal{E}$ : **read** output tapes of the adversary ( $\mathcal{A}$  or  $\mathcal{S}$ ) and any uncorrupted (dummy) parties; then **write** on the input tape of one party (the adversary  $\mathcal{A}$  or  $\mathcal{S}$  or any uncorrupted (dummy) parties).
- Adversary  $\mathcal{A}$ : **read** its own tapes and the outgoing communication tapes of all parties; then **deliver** a pending message to party by writing it on the recipient's ingoing communication tape *or* **corrupt** a party (which becomes inactive: its tapes are given to  $\mathcal{A}$  and  $\mathcal{A}$  controls its actions from this point on, and  $\mathcal{E}$  is notified of the corruption).
- Real-world party  $P_i$ : only follows its code (potentially writing to its output tape or sending messages via its outgoing communication tape).
- Dummy party  $\tilde{P}_i$ : acts only as a simple relay with the ideal functionality  $\mathcal{F}$ , copying inputs from its input tape to its outgoing communication tape (to  $\mathcal{F}$ ) and any messages received on its ingoing communication tape (from  $\mathcal{F}$ ) to its output tape.
- Adversary  $\mathcal{S}$ : **read** its own input tape and the public headers (see below) of the messages on  $\mathcal{F}$ 's and dummy parties' outgoing communication tapes; then **deliver** a message to  $\mathcal{F}$  from a dummy party or vice versa by copying it from the sender's outgoing communication tape to the recipient's incoming communication tape *or* **send** its own message to  $\mathcal{F}$  by writing on the latter's incoming communication tape *or* **corrupt** a dummy party (which becomes inactive: its tapes are given to  $\mathcal{S}$  and  $\mathcal{S}$  controls its actions from this point on, and  $\mathcal{E}$  and  $\mathcal{F}$  are notified of the corruption).
- Ideal functionality  $\mathcal{F}$ : **read** incoming communication tape; then **send** any messages specified by its definition to the dummy parties and/or adversary  $\mathcal{S}$  by writing to its outgoing communication tape.

**Definition 6.** We say a protocol  $\Pi$  UC-realizes an ideal functionality  $\mathcal{F}$  if for any PPT adversary  $\mathcal{A}$ , there exists a simulator  $\mathcal{S}$  such that for any environment  $\mathcal{E}$ , the distribution ensembles  $\{\text{REAL}_{\Pi, \mathcal{A}, \mathcal{E}}(\lambda, x)\}_{\lambda \in \mathbb{N}, x \in \{0,1\}^*}$  and  $\{\text{IDEAL}_{\mathcal{F}, \mathcal{S}, \mathcal{E}}(\lambda, x)\}_{\lambda \in \mathbb{N}, x \in \{0,1\}^*}$  are computationally indistinguishable.

### 3 Naysayer Proofs

(Parts of this section are taken/adapted from [SGB24].)

In most blockchains with programming capabilities, e.g., Ethereum [Woo24], developers are incentivized to minimize the storage and computation complexity of on-chain programs. Applications with high compute or storage incur significant fees, commonly referred to as *gas*, to compensate validators in the network. Often, these costs are passed on to users of an application.

High gas costs have motivated many applications to utilize *verifiable computation* [GGP10], off-loading expensive operations to powerful but untrusted off-chain entities who perform arbitrary computation and provide a succinct non-interactive proof (SNARK) that the claimed result is correct. This computation can even depend on secret inputs not known to the verifier in the case of zero-knowledge proofs (i.e., zkSNARKs).

Verifiable computation leads to a paradigm in which smart contracts, while capable of arbitrary computation, primarily act as verifiers and outsource all significant computation off-chain. A motivating application is *rollups*, which combines transactions from many users into a single smart contract which verifies a proof that all have been executed correctly. However, verifying these proofs can still be costly. For example, the StarkEx rollup has spent hundreds of thousands of dollars to date to verify FRI polynomial commitment opening proofs.<sup>7</sup>

We observe that this proof verification is often wasteful. In most applications, provers have strong incentives to only post correct proofs, suffering direct financial penalties (in the form of a lost security deposit) or indirect costs to their reputation and business for posting incorrect proofs. As a result, a significant fraction of a typical layer-1 blockchain’s storage and computation is expended verifying proofs, which are almost always correct.<sup>8</sup>

This state of affairs motivates us to propose a new paradigm called *naysayer proofs*. In this paradigm, the verifier (e.g., a rollup smart contract) optimistically accepts a submitted proof without verifying its correctness. Instead, any observer can check the proof off-chain and, if needed, prove its *incorrectness* to the verifier by submitting a *naysayer proof*. The verifier then checks the naysayer proof and, if it is correct, rejects the original proof. Otherwise, if no party can successfully naysay the original proof before the end of the dispute period, the original proof is accepted. To deter denial of service, naysayers may be required to post collateral, which is forfeited if their naysayer proof is incorrect.

This paradigm potentially saves the verifier work in two ways. First, in the optimistic case, where the proof is not challenged, the verifier does no work at all. We expect this to almost always be the case in practice. Second, even in the pessimistic case, checking the naysayer proof may be much more efficient than checking the original proof (e.g., if the verification fails at a single point, the

<sup>7</sup><https://etherscan.io/address/0x3e6118da317f7a433031f03bb71ab870d87dd2dd>

<sup>8</sup>At the time of this writing, we are unaware of any major rollup service which has posted an incorrect proof in production.

Non-interactive	●	○	●	●
Off-chain original Vrfy	○	●	●	●
Witness-independent resolution	●	◐	○	●
Avoids original Prove	○	●	●	○

Table 1: Trade-offs of verifiable computation (VC), interactive (e.g., Arbitrum [Lab23], Optimism V2 [Opt23a]) and non-interactive (e.g., Optimism V1) fraud proofs, and naysayer proofs.

naysayer proof can just point to that specific step). In other words, the naysayer acts as a helper to the verifier by reducing the cost of the verification procedure in fraudulent cases. At worst, checking the naysayer proof is equivalent to verifying the original proof (this is the trivial naysayer construction).

Naysayer proofs enable other interesting trade-offs. For instance, naysayer proofs might be run at a lower security level than the original proof system. A violation of the naysayer proof system’s soundness undermines the *completeness* of the original proof system. For an application like a rollup service, this results only in a loss of liveness; importantly, the rollup users’ funds would remain secure. Liveness could be restored by falling back to full proof verification.

In Section 3.2, we formally define naysayer proofs and show that every NP language has a logarithmic size and constant-time naysayer proof. In Section 3.3, we provide three concrete examples where naysayer proofs offer significant speedups.

### 3.1 Related Work

A concept related to the naysayer paradigm is *refereed delegation* [FK97]. The idea has found widespread adoption [TR19, KGC<sup>+</sup>18] in the form of “fraud proofs” or “fault proofs” as used in *optimistic rollups* [Eth23b, Lab23, Opt23a]. Like naysayer proofs, fraud proofs work under an optimistic assumption, i.e., a computation is assumed to be correct unless some party challenges it. In case of a challenge, a dispute resolution process ensues between the *challenger* and the *defender*. The parties engage in a *bisection protocol* to locate a single step of the computation whose result they disagree on, and that step is re-executed on-chain to resolve the dispute. To non-interactively resolve disputes, the full computation can instead be re-executed by the on-chain verifier.

We compare classic verifiable computation, fraud proofs, and our new approach in Table 1. **Noemi: Discuss table here. Note that VC and naysayers require running (cost-intensive) underlying prover, something which fraud proofs avoid.** At a high level, in the fraud proof paradigm, a “prover” performs a provisionally accepted computation without any proof of correctness. Any party

can then challenge the correctness of the prover’s *computation*. In the naysayer paradigm, by contrast, the prover supplies a proof with the computation output, which is provisionally accepted. Any party can then challenge the correctness of the *proof*. The naysayer approach offers significant speedups since the verifier’s circuit is typically much smaller than the original computation. Note that there is a slight semantic difference: fraud proofs can definitively show that the computation output is incorrect. In contrast, naysayer proofs can only show that the accompanying proof is invalid—the computation itself may have been correct.

Furthermore, for fraud proofs, the full computation input (the witness) must be made available to the verifier and potential challengers. Naysayer proofs, on the other hand, can be verified using only the statement and proof. Hence, naysayer proofs work naturally with zero-knowledge proofs. This can also lead to crucial savings if the witness is very large (e.g., transaction data for a rollup).

The fraud proof design pattern has been applied in an application-specific way in many blockchain applications besides optimistic rollups, including the Lightning Network [PD16], Plasma [PB17], cryptocurrency mixers [SNBB19], and distributed key generation [SJSW19]. We view naysayer proofs as a drop-in replacement for the many application-specific fault proofs, offering an alternative which is both more general and more efficient.

There are three entities in a naysayer proof system. We assume that all parties can read and write to a public bulletin board (e.g. a blockchain).

**Prover** The prover posts a proof  $\pi$  to the bulletin board claiming  $(x, w) \in \mathcal{R}$ .

**Verifier** The verifier does not directly verify the validity of  $\pi$ , rather, it allows everyone to naysay in a pre-defined time window of duration  $T_{\text{nay}}$ . Optimistically, if no one naysays  $\pi$  within time  $T_{\text{nay}}$ , the verifier accepts it. In the pessimistic case, a party (or multiple parties) naysay the validity of  $\pi$  by posting proof(s)  $\pi_{\text{nay}}$ . The verifier checks the validity of each  $\pi_{\text{nay}}$ , and if any of them pass, it rejects the original proof  $\pi$ .

**Naysayer** If  $\text{Vrfy}(\text{crs}, x, \pi) = 0$ , then the naysayer posts a naysayer proof  $\pi_{\text{nay}}$  to the public bulletin board before  $T_{\text{nay}}$  time elapses.

Note that we need to assume a synchronous communication model as we cannot have naysayer proofs in partial synchrony or asynchrony: if the adversary can arbitrarily delay the posting of naysayer proofs, then we cannot enforce soundness of the underlying proofs. Note that synchrony is already assumed by most of the deployed consensus algorithms, e.g., Nakamoto consensus [Nak08]. Furthermore, we assume that the public bulletin board offers censorship resistance for the writers of the bulletin board. Finally, we assume that there is *at least one honest party* who is ready to create and submit naysayer proofs for invalid proofs.

### 3.2 Formal Definitions

We formally introduce the notion of a *naysayer proof*, with the following syntax:

**Definition 7** (Naysayer proof). *Given a non-interactive proof system  $\Pi = (\text{Setup}, \text{Prove}, \text{Vrfy})$  for some NP relation  $\mathcal{R}$ , the corresponding naysayer proof system  $\Pi_{\text{nay}}$  is a tuple of PPT algorithms  $(\text{NSetup}, \text{NProve}, \text{Naysay}, \text{VrfyNay})$  defined as follows:*

$\text{NSetup}(1^\lambda, 1_{\text{nay}}^\lambda) \rightarrow (\text{crs}, \text{crs}_{\text{nay}})$ : *Given security parameters  $1^\lambda$  and  $1_{\text{nay}}^\lambda$  for  $\Pi$  and  $\Pi_{\text{nay}}$ , respectively, output common reference strings  $\text{crs}$  and  $\text{crs}_{\text{nay}}$ . This algorithm might use private randomness.*

$\text{NProve}(\text{crs}, x, w) \rightarrow \pi$ : *Given a statement  $x$  and witness  $w$  such that  $(x, w) \in \mathcal{R}$ , compute  $\pi' \leftarrow \Pi.\text{Prove}(\text{crs}, x, w)$  and  $\text{com}$  a commitment to the evaluation trace of  $\Pi.\text{Vrfy}(\text{crs}, x, \pi')$ , output  $\pi := (\text{com}, \pi')$ .*

$\text{Naysay}(\text{crs}_{\text{nay}}, (x, \pi), \text{aux}_{\text{nay}}) \rightarrow \pi_{\text{nay}}$ : *Given a statement  $x$ ,  $\pi = (\text{com}, \pi')$  where  $\pi'$  is a corresponding (potentially invalid) proof in proof system  $\Pi$ , and auxiliary information  $\text{aux}_{\text{nay}}$ , output a naysayer proof  $\pi_{\text{nay}}$  disputing  $\pi'$ .*

$\text{VrfyNay}(\text{crs}_{\text{nay}}, (x, \pi), \pi_{\text{nay}}) \rightarrow \{0, \perp\}$ : *Given a statement-proof pair  $(x, \pi = (\text{com}, \pi'))$  and a naysayer proof  $\pi_{\text{nay}}$  disputing  $\pi$ , output a bit indicating whether evidence against  $\pi$  is sufficient to reject  $\pi$  (0) or inconclusive ( $\perp$ ).*

A trivial naysayer proof system always exists in which  $\pi_{\text{nay}} = \emptyset$ ,  $\pi = (\perp, \pi')$ , and  $\text{VrfyNay}$  simply runs the original verification procedure. We say a proof system  $\Pi$  is *efficiently naysayable* if there exists a corresponding naysayer proof system  $\Pi_{\text{nay}}$  such that  $\text{VrfyNay}$  is asymptotically faster than  $\text{Vrfy}$ . If  $\text{VrfyNay}$  is only concretely faster than  $\text{Vrfy}$ , we say  $\Pi_{\text{nay}}$  is a *weakly efficient* naysayer proof. Note that some proof systems already have constant proof size and verification time [Gro16, Sch90] and therefore can, at best, admit only weakly efficient naysayer proofs. Moreover, if  $\text{aux}_{\text{nay}} = \emptyset$ , we say  $\Pi_{\text{nay}}$  is a *public* naysayer proof.

**Definition 8** (Naysayer correctness). *Given a proof system  $\Pi$ , a naysayer proof system  $\Pi_{\text{nay}}$  is correct if, for all honestly generated  $\text{crs}, \text{crs}_{\text{nay}}$ , all statements  $x$ , and all invalid proofs  $\pi$ ,  $\text{Naysay}$  outputs a valid naysayer proof  $\pi_{\text{nay}}$ :*

$$\Pr \left[ \text{VrfyNay}(\text{crs}_{\text{nay}}, (x, \pi), \pi_{\text{nay}}) = 0 \mid \begin{array}{l} (\text{crs}, \text{crs}_{\text{nay}}) \leftarrow \text{NSetup}(1^\lambda, 1_{\text{nay}}^\lambda) \wedge \\ \text{Vrfy}(\text{crs}, x, \pi) = 0 \wedge \\ \pi_{\text{nay}} \leftarrow \text{Naysay}(\text{crs}_{\text{nay}}, (x, \pi), \text{aux}_{\text{nay}}) \end{array} \right] = 1. \quad (2)$$

**Definition 9** (Naysayer soundness). *Given a proof system  $\Pi$ , a naysayer proof system  $\Pi_{\text{nay}}$  is sound if, for all PPT adversaries  $\mathcal{A}$  and for all  $x, \text{aux}$ , honestly generated  $\text{crs}, \text{crs}_{\text{nay}}$ , and correct proofs  $\pi$ ,  $\mathcal{A}$  produces a verifying naysayer proof  $\pi_{\text{nay}}$  with at most negligible probability:*

$$\Pr \left[ \text{VrfyNay}(\text{crs}_{\text{nay}}, (x, \pi), \pi_{\text{nay}}) = 0 \mid \begin{array}{l} (\text{crs}, \text{crs}_{\text{nay}}) \leftarrow \text{NSetup}(1^\lambda, 1_{\text{nay}}^\lambda) \wedge \\ \text{Vrfy}(\text{crs}, x, \pi) = 1 \wedge \\ \pi_{\text{nay}} \leftarrow \mathcal{A}(\text{crs}_{\text{nay}}, (x, \pi), \text{aux}_{\text{nay}}) \end{array} \right] \leq \text{negl}(\lambda_{\text{nay}}). \quad (3)$$

We distinguish between two types of naysayer proofs as follows.

**Type 1.** A prover of an NP-relation  $\mathcal{R}_{\mathcal{L}}$  posts  $(x, \pi)$  to the public bulletin board claiming that  $x \in \mathcal{L}$ . If the proof  $\pi$  is invalid with respect to the statement  $x$ , i.e.,  $\text{Vrfy}(\text{crs}, x, \pi) = 0$ , then naysayer provers convince the resource-constrained verifier by sending a  $\pi_{\text{nay}}$  that this is indeed the case, i.e.,  $\text{VrfyNay}(\text{crs}_{\text{nay}}, (x, \pi), \pi_{\text{nay}}) = 0$ .

**Type 2.** This family of naysayer proofs is even more efficient in the optimistic case, as the prover *only sends the instance*  $x$  and no proofs at all, claiming without evidence that  $(x, w) \in \mathcal{R}$ . On the other hand, if the prover’s assertion is incorrect, i.e.,  $(x, w) \notin \mathcal{R}$ , then a naysayer prover provides the correct statement  $x'$  such that  $(x', w) \in \mathcal{R}$  and a corresponding “regular” proof  $\pi$  such that  $\text{Vrfy}(\text{crs}, x', \pi) = 1$ . For example, in the case of rollups, the (public) witness  $w$  is the set of transactions in the rollup, and the statement  $x = (\text{st}, \text{st}')$  is the updated rollup state after applying the batch  $w$ . Therefore, an incorrect assertion represents an incorrect application of the update  $w$ . The correction  $x'$  is the result of the proper application of  $w$ .

We conjecture that in most applications, in the worst case, type-2 naysayer proofs are more costly than type-1 naysayer proofs (both compute and storage). It is an interesting open question which applications are more suited to type-1 or type-2 naysayer proofs considering both optimistic and pessimistic costs. To thoroughly model this question, one must take into account the verifier’s compute cost, the (naysayer) proof storage costs, as well as the probability of the prover sending an invalid proof. We leave this problem to future work. In the rest of Section 3, we solely focus on type-1 naysayer proofs.

*todo: Update this framing. Makes more sense to say that every proof system (succinct or not) has a succinct—i.e., log-size and constant-time verifiable—naysayer proof. (Then the concrete succinctness of the base proof system determines whether the naysayer is efficient/weakly efficient/etc.) Noemi: This assumes the verification algorithm is already in circuit-form, so not sure this works. CTB Rev1 suggested the phrasing “for all NP, the trivial proof system has a constant-time and log-size naysayer”. Finally, we show that for every NP language, there exists a logarithmic-size naysayer proof with constant verification time (i.e., a succinct naysayer proof).*

**Lemma 2.** *For every NP language  $\mathcal{L}$  with relation  $\mathcal{R}_{\mathcal{L}}$ , *todo: change to CSAT specifically* there exists a naysayer proof system  $\Pi_{\text{nay}}$  with logarithmic-sized proofs  $\pi_{\text{nay}}$  and constant-time verifier.*

*Proof.* For any NP language  $\mathcal{L}$ , there exists a non-interactive proof system  $\Pi = (\text{Setup}, \text{Prove}, \text{Vrfy})$  for  $\mathcal{R}_{\mathcal{L}}$  where  $\text{Vrfy}(\text{crs}, \cdot, \cdot)$  can be represented as a boolean circuit  $C$  of size  $\text{poly}(|x|)$  [LS91]. Recall that for all  $(x, w) \in \mathcal{R}_{\mathcal{L}}$  and  $\text{crs} \leftarrow \Pi.\text{Setup}(1^\lambda)$ , by correctness, we have that if  $\pi' \leftarrow \Pi.\text{Prove}(\text{crs}, x, w)$  then  $C(x, \pi') = 1$ . Therefore, if there is some gate of  $C$  for which the wire assignment is inconsistent, then the proof  $\pi'$  is incorrect. To naysay, i.e., to show the

incorrectness of  $\pi'$ , the naysayer simply provides the index of the inconsistent gate. Recall that the verifier has access to the wire assignments of  $C(x, \pi')$  as part of  $\pi$  (see Definition 7). The verifier then checks whether the wire assignments of  $C(x, \pi')$  are consistent with a correct evaluation of the gate, which is a constant-time operation assuming constant-time indexing into the wire assignments. Furthermore, the naysayer proof consists only of the gate index, which is logarithmic in the circuit size, i.e., succinct.

*todo:* The above argues completeness (that if a proof is incorrect, we can naysay it). Need also to argue soundness (that if a proof is correct, we cannot give a convincing naysayer proof).  $\square$

**Theorem 1.** *Every efficient proof system  $\Pi$  (i.e., with a polynomial-time verification algorithm) has a succinct naysayer proof.*

*Proof.* Given any proof system  $\Pi$ , one can represent the  $\text{Vrfy}(\text{crs}, \cdot, \cdot)$  algorithm as a circuit and apply the above lemma to obtain a succinct naysayer proof.  $\square$

*Noemi:* Notice that the naysayer proof consists of an *integer* index (which may only require a few bits to represent). So, even though it is asymptotically logarithmic, in fact it may actually be smaller than many “regular” proofs which consist of some group elements (which are normally at least  $\lambda$  bits long). – Need to check this with some common circuit sizes (e.g., the STARK verification circuit) and group element sizes (e.g., BN254 curve G1 element or other).

### 3.3 Applications

The naysayer proof paradigm is generally applicable for proof systems with multi-round amplification, repetitive structure (e.g., multiple bilinear pairing checks [GWC19]), or recursive reduction (e.g., Pietrzak’s proof of exponentiation [Pie19]). In this section, we highlight three example constructions of naysayer proofs.

#### 3.3.1 FRI Polynomial Commitment Scheme

The FRI polynomial commitment scheme [BBHR18] is used as a building block in many non-interactive proof systems, including STARKs [BCGT13]. Below, we describe only the parts of FRI relevant to our discussion. The FRI commitment to a polynomial  $p(x) \in \mathbb{F}^{\leq d}[X]$  is the root of a Merkle tree with  $\rho^{-1}d$  leaves. Each leaf is an evaluation of  $p(x)$  on the set  $L_0 \subset \mathbb{F}$ , where  $\rho^{-1}d = |L_0| \ll |\mathbb{F}|$ , for  $0 < \rho < 1$ . We focus on the verifier’s cost in the opening proof of the FRI polynomial commitment scheme as applied in the STARK IOP. Let  $\delta$  be a parameter of the scheme such that  $\delta \in (0, 1 - \sqrt{\rho})$ . The prover sends the verifier  $\log_2(|L_0|)$  messages. The FRI opening proof’s verifier queries the prover’s each message  $\lambda / \log_2(1/(1 - \delta))$  times to ensure  $2^{-\lambda}$  soundness error. In each query, the verifier needs to check a Merkle-tree authentication path consisting of  $\mathcal{O}(\log_2(\rho^{-1}d))$  hashes. Therefore, the overall STARK proof consists of  $\mathcal{O}(\lambda \log_2(\rho^{-1}d) / \log_2(1/(1 - \delta)))$  hashes.

The overall STARK proof is invalid if any of the individual Merkle proofs is invalid. Therefore a straightforward naysayer proof  $\pi_{\text{nay}}^{\text{FRI}} = (i, z_i)$  need only point to the  $i$ th node in one of the Merkle proofs, where the hash values of the children nodes  $x, y$  and their parent node  $z \neq H(x, y)$  do not match in one of the incorrect Merkle authentication paths. The naysayer verifier only needs to compute a single hash evaluation  $H(x, y) = z_i$  and check  $z_i \neq z$ . Thus, the naysayer proof for FRI has constant-size and can be verified in constant-time.

### 3.3.2 Post-quantum Signature Schemes

With the advent of account abstraction [Eth23a], Ethereum users can define their own preferred digital signature schemes, including post-quantum signatures as recently standardized by NIST [BHK<sup>+</sup>19, DKL<sup>+</sup>18, PFH<sup>+</sup>22]. In all known schemes, post-quantum signatures or public keys are substantially larger than their classical counterparts. Since post-quantum signatures are generally expensive to verify on-chain, they are prime candidates for the naysayer proof paradigm.

**CRYSTALS-Dilithium [DKL<sup>+</sup>18].** The verifier of this scheme checks that the following holds for signature  $\sigma = (\mathbf{z}, c)$ , public key  $pk = (\mathbf{A}, \mathbf{t})$ , and message  $M$ :

$$\forall i : \|z_i\|_{\infty} \leq C \wedge \mathbf{A}\mathbf{z} - c\mathbf{t} = \mathbf{w} \wedge c = H(M\|\mathbf{w}), \quad (4)$$

where  $C$  is a constant,  $\mathbf{A} \in R_q^{k \times l}$ , and  $\mathbf{z}, \mathbf{t}, \mathbf{w} \in R_q^k$  for the polynomial ring  $R_q := \mathbb{Z}_q[x]/(X^{256} + 1)$ . Notice that the checks in Equation (4) are efficiently naysayable. In fact, the naysayer prover must show that the following holds:

$$\exists i : \|z_i\|_{\infty} > C \vee \mathbf{A}\mathbf{z} - c\mathbf{t} \neq \mathbf{w} \vee c \neq H(M\|\mathbf{w}). \quad (5)$$

If the first check fails, then the naysayer prover shows an index  $i$  for which the infinity norm of one of the polynomials in  $\mathbf{z}$  is large. If the second check fails, then the naysayer prover can point to the  $i$ th row of the vector  $\mathbf{w}$ , where matrix-vector multiplication fails and verify only that row. Finally, if the last check fails, then the naysayer verifier just needs to recompute a single hash evaluation.

**SPHINCS+ [BHK<sup>+</sup>19].** The signature verifier in SPHINCS+ checks several Merkle authentication proofs, requiring hundreds of hash evaluations. A constant-size and -time naysayer proof can be easily devised akin to the naysayer proof described in Section 3.3.1. The naysayer prover simply points to the hash evaluation in one of the Merkle-trees where the signature verification fails.

### 3.3.3 Verifiable Shuffles

Verifiable shuffles are applied in many (blockchain) applications such as single secret leader election algorithms [BEHG20], mix-nets [Cha81], cryptocurrency mixers [SNBB19], and e-voting [Adi08]. The state-of-the-art proof system for proving the correctness of a shuffle is due to Bayer and Groth [BG12]. Their

proof system is computationally heavy to verify on-chain as the proof size is  $\mathcal{O}(\sqrt{n})$  and verification time is  $\mathcal{O}(n)$ , where  $n$  is the number of shuffled elements.

Most shuffling protocols (of public keys, re-randomizable commitments, or ElGamal ciphertexts) admit a succinct naysayer proof if the naysayer knows at least one of the shuffled elements. Let us consider the simplest case of shuffling public keys. We want to prove membership in the following NP language:

$$\mathcal{R}_{perm} := \{(g^{w_i}, g^{r \cdot w_{\sigma(i)}})_{i=1}^n, g^r; \sigma, r \mid \forall i : w_i, r \in_R \mathbb{F}_p, g \in \mathbb{G}, \sigma \in_R \text{Perm}(n)\}, \quad (6)$$

where  $\text{Perm}(n)$  is the set of all permutations  $f : [n] \rightarrow [n]$ . Suppose the naysayer knows that for  $j \in [n]$ , the prover did not correctly include  $g^{r \cdot w_j}$  in the shuffle. The naysayer can prove this by showing that  $(g, g^{w_j}, g^r, g^{r \cdot w_j}) \in \mathcal{R}_{DH} \wedge g^{r \cdot w_j} \notin (\cdot, g^{r \cdot w_{\sigma(i)}})_{i=1}^n$ , where  $\mathcal{R}_{DH}$  is the language of Diffie-Hellman tuples. One can show that a tuple is a Diffie-Hellman tuple with a proof of knowledge of discrete logarithm equality [CP93]. However, the naysayer must know the discrete logarithm  $w_j$  to produce such a proof. Unlike our previous examples, which were publicly naysayable, this is a privately naysayable proof since the naysayer algorithm takes auxiliary input  $w_j$ . With the right data structure for the permuted list (e.g., a hash table), both of the above conditions can be checked in constant-time with a constant-size naysayer proof, resulting in exponential savings compared to directly verifying the original Bayer-Groth shuffle proof.

### 3.3.4 zkVMs

Noemi: Given an underlying zkVM, you can define a corresponding naysayer proof based on the `zkVM.Vrfy` circuit — with the rise of zkVMs, should mention this. This is still “application-specific”, since the naysayer proof depends on what zkVM is used (on its design/proof system). But in practice it’s more “general-purpose”. However, I think naysayer proofs are inherently application-specific since they rely on the structure of the verification circuit. But if we, as an area, start using only a few common verification circuits (e.g., adopting a few standard zkVMs), then the naysayer proof system can be reused.

Noemi: update: not sure if it makes sense to talk about a `zkVM.Vrfy` circuit — they’re generally just some proof system’s verification procedure, e.g. the RISC Zero zkVM is running a STARK. Just talk about general naysaying by committing to a verification trace—and mention zkVMs somewhere as an example—then talk about particular languages where the verification trace is not needed because the structure is repetitive (i.e., conjunctions).

### 3.3.5 Evaluation

We evaluate the asymptotic cost savings for the verifiers in the four examples discussed in Sections 3.3.1 to 3.3.3. Note that naysayer proofs allow an exponential speedup for the verifier for verifiable shuffles and a logarithmic speedup for the FRI polynomial commitment opening proof verifier, see Table 2. For CRYSTALS-Dilithium, we can only claim weakly efficient naysayer proofs, as

there is no asymptotic gap in the complexity in certain branches of the signature verification circuit and the naysayer prover algorithm, cf. Equations (4) and (5).

	FRI Opening	CRYSTALS-D.	SPHINCS+	Shuffle proof
$\pi$ storage	$\mathcal{O}(\lambda \log^2(d))\mathbb{H}$	$\mathcal{O}(\lambda)\mathbb{F}$	$\mathcal{O}(\lambda)\mathbb{F}$	$\mathcal{O}(\sqrt{n})\mathbb{G}$
$\text{Vrfy}(\pi)$ compute	$\mathcal{O}(\lambda \log^2(d))\mathbb{H}$	$\mathcal{O}(\lambda)\mathbb{F} + 1\mathbb{H}$	$\mathcal{O}(\lambda)\mathbb{H}$	$\mathcal{O}(n)\mathbb{G}$
$\pi_{\text{nay}}$ storage	$1\mathbb{F}$	$1\mathbb{F} \vee 1\mathbb{F} \vee 1\mathbb{F}$	$1\mathbb{F}$	$2\mathbb{G} + 1\mathbb{F}$
$\text{NVrfy}(\pi_{\text{nay}})$ compute	$1\mathbb{H}$	$\mathcal{O}(\lambda)\mathbb{F} \vee \mathcal{O}(\lambda)\mathbb{F} \vee 1\mathbb{H}$	$1\mathbb{H}$	$4\mathbb{G}$

Table 2: Cost savings of the naysayer paradigm for the example applications in Section 3.3. In FRI, let  $\deg(p(x)) = d$ . For the Bayer-Groth shuffle argument [BG12], we consider  $n$  shuffled public keys (or ciphertexts).  $\mathbb{F}, \mathbb{G}$  denotes field/group elements or field/group operations, respectively.  $\mathbb{H}$  denotes hashing operations. **todo: Can I get some estimated numbers here by looking at the implementations/papers of the underlying schemes, and then just the field/group element sizes in the relevant curves for the naysayer?**

### 3.4 Storage Considerations

We assumed in our evaluation that the naysayer verifier can read the instance  $x$ , the original proof  $\pi$ , and the naysayer proof  $\pi_{\text{nay}}$  entirely. Note that in the pessimistic case, the verifier requires increased storage (for  $\pi_{\text{nay}}$ ) but only needs to compute  $\text{VrfyNay}$  instead of  $\text{Vrfy}$ . A useful naysayer proof system should compensate for increased storage by considerably reducing verification costs.

In either case, this approach of storing all data on chain may not be sufficient in blockchain contexts where storage is typically very costly. Blockchains such as Ethereum differentiate costs between persistent storage (which we can call  $S_{\text{per}}$ ) and “call data” ( $S_{\text{call}}$ ), which is available only for one transaction and is significantly cheaper as a result. Verifiable computation proofs, for example, are usually stored in  $S_{\text{call}}$  with only the verification result persisted to  $S_{\text{per}}$ .

Some applications now use a third, even cheaper, tier of data storage, namely off-chain *data availability services* ( $S_{\text{DA}}$ ), which promise to make data available off-chain but which on-chain contracts have no ability to read. Verifiable storage, an analog of verifiable computation, enables a verifier to store only a short commitment to a large vector [CF13, Mer88] or polynomial [KZG10], with an untrusted storage provider ( $S_{\text{DA}}$ ) storing the full values. Individual data items (elements in a vector or evaluations of the polynomial) can be provided as needed to  $S_{\text{call}}$  or  $S_{\text{per}}$  with short proofs that they are correct with respect to the stored commitment.

This suggests an optimization for naysayer proofs in a blockchain context: the prover posts only a binding commitment  $H(\pi)$ , which the contract stores in  $S_{\text{per}}$ , while the actual proof  $\pi$  is stored in  $S_{\text{DA}}$ . We assume that potential naysayers can read  $\pi$  from  $S_{\text{DA}}$ . In the optimistic case, the full proof  $\pi$  is

Approach	NI	No TTPs	Efficient	Tally privacy	Ev. ballot privacy

\* when using class groups

Table 3: Qualitative comparison of major cryptographic approaches for designing private auction/voting schemes. NI = non-interactive, Ev. = everlasting. [AOZZ15, CJSS21] require a trusted setup but no TTP. Everlasting ballot privacy can be added to our approach via an extension (Section 4.10).

never written to the more-expensive  $S_{\text{call}}$  or  $S_{\text{per}}$ . In the pessimistic case, when naysaying is necessary, the naysayer must send openings of the erroneous proof elements to the verifier (in  $S_{\text{call}}$ ). The verifier checks that these data elements are valid with respect to the on-chain commitment  $H(\pi)$  stored in  $S_{\text{per}}$ . Note that in some naysayer proof systems which don’t require reading all of  $\pi$ , even this pessimistic case will offer significant savings over storing all of  $\pi$  in  $S_{\text{call}}$ . An important future research direction is to investigate this optimized storage model’s implications and implementation details.

## 4 On-chain Voting and Auctions

(Parts of this section are taken/adapted from [GSZB24].)

**Special Notation** We will use  $n$  as the number of users,  $m$  as the number of candidates, and  $w$  as the maximum weight to be allocated to any one candidate in a ballot/bid ( $n, m, w \in \mathbb{N}$ ). For simplicity and without loss of generality, we assume the user identities are unique integers  $i \in [n]$ . We generally use  $i \in [n]$  to index users and  $j \in [m]$  for candidates.

Auctions and voting are essential applications of Web3. For example, decentralized marketplaces run auctions to sell digital goods like non-fungible tokens (NFTs) [Ope23] or domain names [XWY<sup>+</sup>21], while decentralized autonomous organizations (DAOs) deploy voting schemes to enact decentralized governance [Opt23b]. Most auction or voting schemes currently deployed on blockchains, e.g., NFT auctions on OpenSea or Uniswap governance [FMW22], lack bid/ballot privacy. This can negatively influence user behavior, for example, by vote herding or discouraging participation [EL04, GY19, SY03]. The lack of privacy can cause surges in congestion and transaction fees as users try to outbid each other to participate, a negative externality for the entire network.

Existing private voting protocols [PE23, GG22, Pria] achieve privacy at the cost of introducing a trusted authority who is still able to view all submis-

sions. Alternatively, the only private *and* trustless auction in deployment we are aware of [XWY+21] uses a two-round commit-reveal protocol: in the first round, every party commits to their bid, and in the second round they open the commitments and the winner can be determined. Other protocols relying on more heavyweight cryptographic building blocks have been proposed in the literature. We summarize the various approaches for private voting and auctions in Table 3. Unfortunately, all of them suffer from at least one of the following limitations, hindering widespread adoption:

**Interactivity.** Interactivity is a usability hurdle that often causes friction in the protocols’ execution. Mandatory bid/ballot reveals are also a target for censorship. A malicious party can bribe the block proposers to exclude certain bids or ballots until the auction/voting ends [PRF23].

**Trusted third party (TTP).** Many protocols [PE23] use a trusted coordinator to tally submissions during the voting/bidding phase. This introduces a strong assumption which is at odds with the trustless ethos of the blockchain ecosystem.

**Inefficiency.** Compute and storage costs are substantial bottlenecks in decentralized applications running on a public blockchain. Some approaches [CGGI16, dLNS17] avoid the previous pitfalls by relying on complex cryptographic primitives such as fully-homomorphic encryption (FHE), whose overheads are impractical in the blockchain setting.

## 4.1 Related Work

The cryptographic literature on both voting schemes and sealed-bid auctions is enormous, dating to the 1990s. However, most of these schemes are unsuitable for a fully decentralized and trust-minimized setting due to their inefficiency or reliance on trusted parties, i.e., tally authorities, servers running the public bulletin board, auctioneers, etc. Below, we review auction and voting protocols that use a blockchain as the public bulletin board.

**Voting.** The study of voting schemes for blockchain applications dates to at least 2017, when McCorry et al. [?] proposed a “boardroom” voting protocol for DAO governance. The main disadvantage of their protocol is that the entire protocol can be aborted due to a single party. Groth [?] and Boneh et al. [?] develop techniques to create ballot correctness proofs for various voting schemes. These protocols all have proofs with size linear in the number of candidates. We break this barrier by applying polynomial commitments and assuming a transparent, lightweight pre-processing phase. Applying HTLPs to voting was suggested when they were proposed by Malavolta and Thyagarajan [?]. However, they left the details of making such a protocol practical, secure, and efficient to future work. We aim to fill this gap with our techniques for various election types and our EVM implementation.

**Auctions.** Auctions are a natural fit for blockchains and were suggested as early as 2018 [?], albeit with a *trusted auctioneer*. Bag et al. introduced SEAL, a privacy-preserving sealed-bid auction scheme without auctioneers [?]. However, their protocol employs two rounds of communication since they apply the Hao-Zielinski Anonymous Veto network protocol [?]. Tyagi et al. proposed Riggs [?], a fair non-interactive auction scheme using timed commitments [?, §6]. This is perhaps the closest work to ours in implementing auctions (but not voting) in a fully decentralized setting using time-based cryptography. However, their design does not utilize homomorphism to combine puzzles, and as a result the gas costs are high. To achieve practicality Riggs relies on an optimistic second round in which users voluntarily open their puzzles. Chvojka et al. suggest a TLP-based protocol for both e-voting and auctions [?]. Their protocol has a per-auction trusted setup. In Section 4.10.5, we propose using HTLPs for distributed setup to reduce the trust assumption, which may be of independent interest.

**Time-based cryptography.** Time-based cryptography, which uses inherently sequential functions to delay the revelation of information, also has a lengthy history dating to Rivest, Shamir, and Wagner’s 1996 proposal of time-lock encryption [?]. Numerous variants have emerged since then, including timed commitments [?], proofs-of-sequential-work [?], VDFs [?], and homomorphic time-lock puzzles [?], which we employ here. For a recent survey, we refer the reader to Medley et al. [?]. The only practical work we know of taking advantage of HTLPs is Bicorn [?], which builds a distributed randomness beacon with a single aggregate HTLP for an arbitrary number of entropy contributors.

Delay encryption constitutes the most recent development in time-based cryptography. Delay encryption allows time-lock encryption of a message to an identity by combining identity-based encryption with inherently sequential computation. This cryptographic primitive was introduced by Burdges and De Feo [?]. However, their isogeny-based construction has enormous memory requirements ( $\approx 12$  TiB), making their scheme impractical.

One can emulate time-based cryptography by applying stronger assumptions instead of assuming the sequentiality of repeated modular squaring. McFly [?] and tlock [?] build time-lock encryption from threshold trust, i.e., by assuming that a subset of signers intermittently and reliably releases a threshold signature on the current timestamp. Even though this is a stronger assumption, we view this as a promising alternative research direction. For instance, enabling the aggregation of multiple time-lock ciphertexts could make timelock encryption especially suitable for voting and auction applications; aggregation is not currently possible in the aforementioned schemes as they lack any homomorphism. Using any resulting homomorphic time-lock encryption schemes to build efficient voting and auction protocols is a further open problem. We leave these questions to future work.

## 4.2 Our Results

We aim to build voting and auction protocols that possess the following distinguishing features compared to prior work.

**Trust-minimization.** In our protocols, we do not want to assume (a quorum of) trusted third parties. The cryptographic voting literature extensively applies trusted parties, for example, to operate a public bulletin board or tally votes. The classic tools used in prior work, e.g. (fully) homomorphic encryption, inherently imply a handful of trusted parties to decrypt the ballots/bids. Apart from the liveness and safety of the blockchain consensus, we solely employ standard cryptographic assumptions.

**One-round protocol.** We argue that usability is one of the major challenges of deploying privacy-preserving voting and auction protocols in practice. Multi-round protocols, e.g., commit-reveal-style protocols, have incentive issues and considerable usability hurdles. We solve these pressing issues with efficient one-round protocols.

**Ballot/bid privacy.** Last but not least, we want to achieve ballot/bid privacy. Our approach naturally provides privacy until the end of the voting/bidding phase. This is sufficient for avoiding selective aborts and censorship, thereby ensuring fairness. Limited privacy can also be a desideratum in certain settings, e.g. in representative democracies where delegates' votes are published to encourage accountability. Alternatively, we show in Section 4.10.1 how we can add everlasting ballot/bid privacy to our protocol without sacrificing our two previously stated goals.

Coercion-resistance, i.e., the adversary's inability to coerce voters to cast specific ballots demanded by the adversary, is a crucial property of voting schemes. In the privacy-respecting e-voting literature, it is well-known that receipt-freeness (since the voters cannot prove how they voted) implies coercion-resistance [BT94]. However, we consider receipt-freeness as a non-goal in our protocol design. Still, we sketch an extension to our framework in Section 4.10.3, where we achieve coercion-resistance via a different pathway than receipt freeness. We leave it to future work to achieve the property of receipt freeness for on-chain voting schemes.

We introduce Cicada, a general framework for practical, privacy-preserving, and trust-minimized protocols for both auctions and voting. Cicada uses time-lock puzzles (TLPs) [RSW96] to achieve *privacy and non-interactivity* in a trustless and efficient manner. A TLP allows a party to “encrypt” a message to the future. Specifically, to recover the solution, one needs to perform a computation that is believed to be inherently sequential, with a parameterizable number of steps. Intuitively, the TLPs play the role of commitments to bids/ballots that any party can open after a predefined time, avoiding the reliance on a second *reveal* round.

Since solving a TLP is computationally intensive, ideally, an efficient protocol would require solving only a sublinear number of TLPs (in the number

of voters/bidders). Cicada achieves this via *homomorphic* TLPs (HTLPs): bids/ballots encoded as HTLPs can be “squashed” into a sublinear number of TLPs. Fully homomorphic TLPs are not practically efficient, but Malavolta and Thyagarajan [MT19] introduced efficient additively and multiplicatively homomorphic TLP constructions which we will describe below. This is clearly enough for simple constructions like first-past-the-post (FPTP) voting, but it remained an open problem how to apply HTLPs to realize more complicated auction and voting protocols, e.g., cumulative voting.

We show how to use HTLPs to build practically efficient, private, and non-interactive protocols for a special class of auction and voting schemes where the tallying procedure can be expressed as a linear function. We show that this limited class nonetheless includes many schemes of interest.

Moreover, we introduce a novel linear HTLP based on the exponential ElGamal cryptosystem [CGS97] over a group of unknown order. This construction is more efficient than the Paillier-based construction [MT19] for a small solution space  $\mathcal{S} \subset \mathbb{Z}_N$ , i.e.,  $\mathcal{S} = \{s : s \in \mathbb{J}_N \wedge s \ll N\}$ . Here a puzzle  $Z$  is constructed as

$$(g^r, h^r y^s) \in (\mathbb{Z}_N^*)^2 \quad (7)$$

where  $g, y \xleftarrow{\$} \mathbb{Z}_N^*$  and again  $h = g^{2^T}$ . This scheme is only practical for small  $\mathcal{S}$  since, in addition to recomputing  $h^r$ , recovering  $s$  requires brute-forcing the discrete modulus of  $y^s$ . We discuss the efficiency trade-off between these two constructions in Section 4.9.

Lifting the multiplicative HTLP of [MT19] (Construction 1) to put  $s$  in the exponent yields a more efficient linear HTLP for a small solution space  $\mathcal{X} \subset \mathbb{Z}_N$ , where  $\mathcal{X} = \{s : s \in \mathbb{J}_N \wedge s \ll N\}$  (Figure 3, changes shown in blue). This can be viewed as a construction based on exponential ElGamal encryption over  $\mathbb{Z}_N^*$ .

**Efficient vector encoding for HTLPs.** In many voting schemes, a ballot consists of a vector indicating the voter’s relative preferences or point allocations for all  $m$  candidates. To avoid solving many HTLPs, it is desirable to encode this vector into a single HTLP, which requires representing the vector as a single integer.

Note that as in the PNS approach, we set  $M = nw+1$  to accommodate homomorphic addition of submissions; homomorphic multiplication, however, would require  $M = w^n + 1$ , and the primes in  $\mathbf{p}$  would therefore be larger as well. Although the RNS has found application in error correction [KPT+22, TC14], side-channel resistance [PFPB18], and parallelization of arithmetic computations [AHK17, BDM06, GTN11, VNL+20], to our knowledge it has not been applied to voting schemes. We will show that RNS is in fact a natural fit for some voting schemes, in particular quadratic voting, where it results in more efficient proofs of ballot correctness.

**Applied NIZKs in Groups of Unknown Order.** We will use *non-interactive zero-knowledge* proofs (NIZKs) to enforce well-formedness of user submissions

while maintaining their secrecy. This prevents users from “poisoning” the aggregate HTLP maintained by the on-chain coordinator. For efficiency, we make use of custom NIZKs (see ??).

Since submissions will be instantiated as HTLPs in our application and all known HTLP constructions use groups of unknown order, our proofs of well-formedness must also operate over these groups. Previous ballot correctness proofs [Gro05] and sigma protocols [Sch90, CP93] generally operate in groups of prime order and cannot directly be applied in groups of unknown order [BCM05]. To circumvent these impossibility results, we follow the blueprint of [BBF19] and instantiate our protocols in generic groups of unknown order [DK02] with a common reference string. We detail our protocols in ??.

Our protocols are both practically efficient, private until the end of the voting/bidding phase, and provably secure, overcoming the following challenges:

### 4.3 System Model

Our system design is illustrated in Figure 4. We envision three types of participants:

**Users.** We simply refer to voters or bidders as *users*. Users submit bids or ballots, which we generically call *submissions*. We assume some external process to establish the set of authorized users (which may be open to all). Once users place their submissions, no further action is required of them.

**On-chain coordinator.** We refer to the tallier/auctioneer as the *coordinator*, typically implemented as a smart contract that collects submissions. The coordinator transparently calculates the winner(s). In the case of an auction, they might also transfer (digital) assets to the winner(s). In an election, they might grant special privileges to the winner.

**Off-chain solver.** Since our protocols apply HTLPs, we assume an untrusted *solver* who unlocks the final HTLP(s) off-chain and submits the solution(s) to the coordinator with proofs of correct opening attached. This could, in principle, be any party, although, in practice, it will likely be one of the parties participating in (or administering) the vote/auction, or a paid marketplace [Aba23, TGB<sup>+</sup>21].

An adversary may attempt to read ballots/bids before the submission phase is complete. This is prevented by the security properties of (H)TLPs (??) assuming the delay  $T$  is longer than the submission phase.

### 4.4 Voting and auction schemes

We recall the specifics of FPTP, approval, range, and cumulative voting, along with single-item sealed bid auctions. The cryptographically relevant details of these schemes (i.e., the valid ballots’ structure: their domain, Hamming weight, and norm) are summarized in Table 4. In ??, we create private voting protocols for these schemes of interest.

	Submission domain	Hamming wt	Norm
<i>Voting schemes</i>			
First-past-the-post	$[0, 1]^m$	1	1
Approval	$[0, 1]^m$	$\leq m$	$\leq m$
Range	$[0, w]^m$	$\leq m$	$\leq wm$
Cumulative	$[0, w]^m$	$\leq m$	$\leq w$
Ranked-choice (Borda)	$\pi([0, m-1])$	$m-1$	$m(m-1)/2$
Quadratic (??)	$[0, \sqrt{w}]^m$	$\leq m$	$\ \mathbf{b}\ _2^2 = \langle \mathbf{b}, \mathbf{b} \rangle = w$
Single-item sealed-bid auction	$[0, w]$	1	$\leq w$
Bayesian truth serum (??)	$[0, 1]^m \times \mathbb{N}^m$	1, 1	$1, \leq m$

Table 4: Requirements for the domain, Hamming weight, and norm of a vector  $\mathbf{b}$  in order for it to be a valid submission in various voting/auction schemes.  $\pi(S)$  denotes the set of permutations of  $S$ . The norm is an  $\ell_1$  norm unless otherwise specified.  $m$  is the number of candidates and  $w$  is the maximum weight which can be assigned to any one candidate.

**Majority, approval, range, and cumulative voting.** In the classic first-past-the-post (FPTP) voting scheme, voters can cast a vote of 1 (support) for one candidate and 0 for all others. A slight generalization of FPTP is approval voting, where users can assign a 1 vote to multiple candidates, i.e., the cast ballot  $s$  can be seen as  $s \in \{0, 1\}^m$ , where  $m$  is the number of causes. A further generalization is range voting, where users can give each candidate up to some weight  $w$  (thus, approval is the special case where  $w = 1$ ). A related scheme is cumulative voting, where users can distribute a total of  $w$  votes (points) among the candidates (now FPTP is a special case where  $w = 1$ ). In each case, each candidate’s points are tallied and the candidate with the highest number is declared the winner.

**Ranked-choice voting.** In a ranked-choice voting scheme, voters can signal more fine-grained preferences among  $m$  candidates by listing them in order of preference. There are multiple approaches to determining the winner, including single transferrable vote (STV) and instant runoff voting (IRV). In this work, we focus on the simpler Borda count version [Eme13], where each voter can cast  $m-1$  points to their first-choice candidate,  $m-2$  points to their second-choice candidate, etc., and the candidate with the most points is the winner. Our protocols can be adapted to similar counting functions, such as the Dowdall system [FG14], via minor modifications.

**Quadratic voting.** In quadratic voting [LW18], each user’s ballot is a vector  $\mathbf{b} = (b_1, \dots, b_m)$  such that  $\langle \mathbf{b}, \mathbf{b} \rangle = \|\mathbf{b}\|_2^2 \leq w$ . Once again, the winner is determined by summing all the ballots and determining the candidate with the most points. Thus, this is also an additive voting scheme. However, proving

ballot well-formedness efficiently in this particular case benefits greatly from the novel application of the residue numeral system (RNS) to private voting (see Section 2.4).

**Single-item sealed-bid auction.** In a sealed-bid auction for a single item (e.g., an NFT or domain name), users submit secret bids to the auction contract. The domain of the bids might be constrained, e.g.,  $b \in \{0, 1\}^k$  (in our implementations  $k \approx 8 - 16$ ; see Section 4.9). Therefore, bidders must prove that their bid is well-formed, i.e., falls into that domain. Once all secret bids are revealed, the contract selects the highest bidder and awards them the auctioned item. The price the winner must pay depends on the auction scheme: e.g., highest bid in a first price auction, second-highest in a Vickrey auction.

#### 4.5 Formalizing Time-Locked Voting and Auction Protocols

We introduce a generic syntax for a time-locked voting/auction protocol. Any such protocol is defined for a base *scoring function*  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  (e.g., second-price auction, range voting), which takes as input  $n$  submissions (bids/ballots)  $s_1, \dots, s_n$  in the submission domain  $\mathcal{X}$  and computes the election/auction result  $\Sigma(s_1, \dots, s_n) \in \mathcal{Y}$ . It is useful to break down the scoring function into the “tally” or aggregation function  $t : \mathcal{X}^n \rightarrow \mathcal{X}'$  and the finalization function  $f : \mathcal{X}' \rightarrow \mathcal{Y}$ , i.e.,  $\Sigma = f \circ t$ . For example, in first-past-the-post voting, the tally function  $t$  is addition, and the finalization function  $f$  is arg max over the final tally/bids.

**Definition 10** (Time-locked voting/auction protocol). *A time-locked voting/auction protocol  $\Pi_\Sigma = (\text{Setup}, \text{Seal}, \text{Aggr}, \text{Open}, \text{Finalize})$  is defined with respect to a base voting/auction protocol  $\Sigma = f \circ t$ , where  $t : \mathcal{X}^n \rightarrow \mathcal{X}'$  and  $f : \mathcal{X}' \rightarrow \mathcal{Y}$ .*

**Setup**( $1^\lambda, T$ )  $\xrightarrow{\S} (\text{pp}, \mathcal{Z})$ . *Given a security parameter  $\lambda$  and a time parameter  $T$ , output public parameters  $\text{pp}$  and an initial time-locked value  $\mathcal{Z}$ .*

**Seal**( $\text{pp}, i, s$ )  $\xrightarrow{\S} (\mathcal{Z}_i, \pi_i)$ . *User  $i \in [n]$  seals its submission  $s \in \mathcal{X}$  into a time-locked submission  $\mathcal{Z}_i$ . It also outputs a proof of well-formedness  $\pi_i$ .*

**Aggr**( $\text{pp}, \mathcal{Z}, i, \mathcal{Z}_i, \pi_i$ )  $\rightarrow \mathcal{Z}'$ . *Given a time-locked running computation  $\mathcal{Z}$ , time-locked submission  $\mathcal{Z}_i$  of user  $i$ , and proof  $\pi_i$ , the transparent contract checks the proof and potentially updates  $\mathcal{Z}$  to  $\mathcal{Z}'$ .*

**Open**( $\text{pp}, \mathcal{Z}$ )  $\rightarrow (\mathbf{s}, \pi_{\text{open}})$ . *Open  $\mathcal{Z}$  to  $\mathbf{s} = t(s_1, \dots, s_n)$ , requiring  $T$  sequential steps, and compute a proof  $\pi_{\text{open}}$  to prove correctness of  $\mathbf{s}$ .*

**Finalize**( $\text{pp}, \mathcal{Z}, \mathbf{s}, \pi_{\text{open}}$ )  $\rightarrow \{y, \perp\}$ . *Given proposed opening  $\mathbf{s}$  of  $\mathcal{Z}$  and proof  $\pi_{\text{open}}$ , the coordinator may reject  $\mathbf{s}$  or compute the final result  $y = f(\mathbf{s}) \in \mathcal{Y}$ .*

We note that the **Setup**( $\cdot$ ) algorithm in our protocols may use private randomness. In particular, our constructions use cryptographic groups (RSA and

Paillier groups) that cannot be efficiently instantiated without a trusted setup (an untrusted setup would require gigantic moduli [San99]). This trust can be minimized by generating the group via a distributed trusted setup, e.g., [BF01, CHI<sup>+</sup>21, DM10]. Alternatively, the HTLPs in our protocols could be instantiated in class groups [TCLM21], which do not require a trusted setup; however, HTLPs in class groups are less efficient and verifying them on-chain would be prohibitively costly (see ??).

A time-locked voting/auction protocol  $\Pi_\Sigma$  must satisfy the following three security properties:

**Correctness.**  $\Pi_\Sigma$  is *correct* if, assuming setup, submission of  $n$  puzzles, aggregation of all  $n$  submissions, and opening are all performed honestly, `Finalize` outputs a winner consistent with the base protocol  $\Sigma$ .

**Definition 11** (Correctness). *We say a voting/auction protocol  $\Pi_\Sigma$  with  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  is correct if for all  $T, \lambda \in \mathbb{N}$  and submissions  $s_1, \dots, s_n \in \mathcal{X}$ ,*

$$\Pr \left[ \begin{array}{c} \text{Finalize}(\text{pp}, \mathcal{Z}_{\text{final}}, \mathcal{S}, \pi_{\text{open}}) \\ = \Sigma(s_1, \dots, s_n) \end{array} \middle| \begin{array}{l} (\text{pp}, \mathcal{Z}) \xleftarrow{\$} \text{Setup}(1^\lambda, T) \wedge \\ (\mathcal{Z}_i, \pi_i) \xleftarrow{\$} \text{Seal}(\text{pp}, i, s_i) \ \forall i \in [n] \wedge \\ \mathcal{Z}_{\text{final}} \leftarrow \text{Aggr}(\text{pp}, \mathcal{Z}, \{i, \mathcal{Z}_i, \pi_i\}_{i \in [n]}) \wedge \\ (\mathcal{S}, \pi_{\text{open}}) \leftarrow \text{Open}(\text{pp}, \mathcal{Z}_{\text{final}}) \end{array} \right] = 1$$

where the aggregation step is performed over all  $n$  submissions in any order.

**Submission privacy.** The scheme satisfies *submission privacy* if the adversary cannot distinguish between two submissions, i.e., bids or ballots. Note that this property is only ensured up to time  $T$ .

**Definition 12** (Submission privacy). *We say that a voting/auction protocol  $\Pi_\Sigma$  with  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  is submission private if for all  $T, \lambda \in \mathbb{N}, i \in [n]$  and all PPT adversaries  $\mathcal{A}$  running in at most  $T$  sequential steps, there exists a negligible function  $\text{negl}(\lambda)$  such that*

$$\Pr \left[ b = b' \middle| \begin{array}{l} (\text{pp}, \mathcal{Z}) \xleftarrow{\$} \text{Setup}(1^\lambda, T) \wedge \\ b \xleftarrow{\$} \{0, 1\} \wedge \\ (\mathcal{Z}_i, \pi_i) \xleftarrow{\$} \text{Seal}(\text{pp}, i, b) \wedge \\ b' \leftarrow \mathcal{A}(\text{pp}, \mathcal{Z}, i, \mathcal{Z}_i, \pi_i) \end{array} \right] \leq \frac{1}{2} + \text{negl}(\lambda).$$

**Non-malleability.** Notice that submission privacy alone does not suffice for security: even without knowing the contents of other puzzles, an adversary could submit a value that depends on other participants' (sealed) submissions. For example, in an auction, one could be guaranteed to win by homomorphically computing an HTLP containing the sum of all the other participants' bids plus a small value  $\varepsilon$ . Therefore, we also require *non-malleability*, which requires that no participant can take another's submission and replay it or “maul” it into a valid submission under its own name.

**Definition 13** (Non-malleability). *We say that a voting/auction protocol  $\Pi_\Sigma$  with  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  is non-malleable if for all  $T, \lambda \in \mathbb{N}$  and all PPT adversaries  $\mathcal{A}$  running in at most  $T$  sequential steps, there exists a negligible function  $\text{negl}(\lambda)$  such that the following probability is bounded by  $\text{negl}(\lambda)[\lambda]$ :*

$$\Pr \left[ \begin{array}{l} \text{Aggr}(\text{pp}, \mathcal{Z}, i, \mathcal{Z}_i, \pi_i) \neq \mathcal{Z} \wedge \\ (i, \cdot, \mathcal{Z}_i, \pi_i) \notin \mathcal{Q} \end{array} \mid \begin{array}{l} (\text{pp}, \mathcal{Z}) \xleftarrow{\$} \text{Setup}(1^\lambda, T) \wedge \\ (i, \mathcal{Z}_i, \pi_i) \leftarrow \mathcal{A}^{\mathcal{O}_{\text{Seal}}(\text{pp}, \cdot, \cdot)}(\text{pp}, \mathcal{Z}) \end{array} \right]$$

where  $\mathcal{O}_{\text{Seal}}(\text{pp}, \cdot, \cdot)$  is an oracle which takes as input any  $j \in [n]$  and  $s_j \in \mathcal{X}$  and outputs  $(\mathcal{Z}_j, \pi_j) \xleftarrow{\$} \text{Seal}(\text{pp}, j, s_j)$ , and  $\mathcal{Q}$  is the set of queries and responses  $(j, s_j, \mathcal{Z}_j, \pi_j)$  to the oracle.

**A note on anonymity.** We consider user anonymity an orthogonal problem. In the applications we have in mind, users can increase their anonymity by using zero-knowledge mixers [PSS19] or other privacy-enhancing overlays, e.g., zero-knowledge sets [Eth19]. Additionally, users can decouple their identities from their ballots by applying a verifiable shuffle [Nef01], although the on-chain verification of a shuffle proof might be prohibitively costly for larger elections. In Section 4.10.1 we describe how our protocols can be extended to achieve bid privacy even after the election ends, thus disclosing nothing besides a user’s (non-)participation.

## 4.6 The Cicada Framework

We present Cicada, our framework for non-interactive private auctions/elections, in Figure 5. Cicada can be applied to voting and auction schemes where the scoring function  $\Sigma = f \circ t$  has a linear tally function  $t$ . The framework uses a linear HTLP (Section 2.2), vector packing scheme (Section 2.4), and matching NIZK (Section 4.7) to ensure correctness of submissions by proving both the well-formedness of the puzzle and the solution’s membership in  $\mathcal{X}$ .

At a high level, Cicada enables auction or voting schemes with the following five steps. *First*, system participants agree on a delay parameter  $T$  and packing parameter  $\ell$ . The **Setup** algorithm outputs HTLP public parameters  $\text{pp}$  (note this might require private randomness) and initializes a set of the tally HTLPs  $\mathcal{Z}$  containing zeros. *Second*, a user  $i$  uses the **Seal** algorithm to encode their submission (a bid or ballot)  $\mathbf{v}_i$  into (a set of) HTLP(s)  $\mathcal{Z}_i$ . **Seal** also outputs a NIZK  $\pi_i$  proving that the submission  $\mathcal{Z}_i$  is well-formed, i.e., is in the domain  $\mathcal{X}$  of the scoring function  $\Sigma$ . Users will send these submissions and corresponding proofs to the on-chain coordinator. *Third*, the coordinator (Cicada smart contract) runs **Aggr** to verify the user-submitted proof  $\pi_i$ , and if it is valid, aggregate the user submission  $\mathcal{Z}_i$  into the tally HTLPs  $\mathcal{Z}$ , resulting in updated tally HTLP(s)  $\mathcal{Z}'$ . *Fourth*, after the voting/bidding period has ended, any party can open the tally HTLPs  $\mathcal{Z}$  off-chain by running **Open**, which outputs the opening(s)  $\mathcal{S}$  of the tally HTLP(s)  $\mathcal{Z}$  along with a proof of correct opening  $\pi_{\text{open}}$  (using a proof of solution PoS, see Section 4.7). The off-chain solver will send  $\mathcal{S}, \pi_{\text{open}}$  to the

contract. *Fifth*, the on-chain contract runs `Finalize` to verify the correctness of  $\mathcal{S}$  by checking  $\pi_{\text{open}}$ . If the check passes, it computes the auction/election winner(s) as  $y = f(\mathbf{v})$ .

Intuitively, submission privacy follows from the security of the HTLP and zero-knowledge of the NIZK used: the submission can't be opened before time  $T$  and none of the proofs leak any information about it. Non-malleability is enforced by requiring the NIZK to be a proof of knowledge and including the user's identity  $i$  in the instance to prove, e.g., including it in the hash input of the Fiat-Shamir transform. This prevents a malicious actor from replaying a different user's ballot correctness proof.

As we will see next, this captures many common schemes such as cumulative voting and sealed-bid auctions. Cicada introduces a crucial design choice via the packing parameter  $\ell \in [m]$ , which defines a storage-computation trade-off that we detail in Section 4.9.

**Additive voting.** Many common voting schemes are “additive”, meaning each ballot (a length- $m$  vector) is simply added to the tally, and a finalization function  $f$  is applied to the tally after the voting phase has ended to determine the winner. Additive voting schemes include first-past-the-post (FPTP), approval, range, and cumulative voting. Simple ranked-choice voting schemes, e.g., Borda count [Eme13], are also additive, differing only in what qualifies as a “proper” ballot (restrictions on vector entry domain, vector norm, etc.; see Table 4). Thus, we can use Cicada to instantiate private voting protocols for all these schemes.

**Theorem 2.** *Given a linear scoring function  $\Sigma$ , a secure NIZKPoK NIZK and proof of solution PoS, a secure HTLP, and a packing scheme (PS<sub>Setup</sub>, Pack, Unpack), the Cicada protocol  $\Pi_\Sigma$  (Figure 5) is a secure time-locked voting/auction protocol.*

*Proof.* For simplicity, we give a proof for the simple case of  $\mathcal{X} = [0, 1]$ , i.e., submissions consist of a single bit, but our argument generalizes to larger domains  $\mathcal{X}$ . Let  $n \in \mathbb{N}$  be the number of users.

The correctness of the Cicada framework (cf. Definition 11) follows by construction and from the correctness of the underlying building blocks (i.e., soundness in the case of the proof systems).

Next, we prove submission privacy. Let  $\text{ExpSPriv}_{\Pi_\Sigma}^A(\lambda, T, i)$  be the original submission privacy game for the Cicada scheme  $\Pi_\Sigma$  with  $T$ -bounded adversary  $\mathcal{A}$ , cf. Definition 12. We define a series of hybrids to show that

$$\Pr[\text{ExpSPriv}_{\Pi_\Sigma}^A(\lambda, T, i) = 1] \leq \text{negl}(\lambda)$$

for all  $\lambda, T \in \mathbb{N}$  and  $i \in [n]$ .

$\mathcal{H}_0$ : This is the original game  $\text{ExpSPriv}_{\Pi_\Sigma}^A(\lambda, T, i)$ , where  $Z_i \leftarrow \text{HTLP.Gen}(b)$  and  $\pi_i \leftarrow \text{NIZK.Prove}(i, Z_i, b)$ .

$\mathcal{H}_1$ : Replace  $\pi$  with  $\tilde{\pi} \leftarrow \text{NIZK.S}(i, Z_i)$ .  $\mathcal{H}_1$  is indistinguishable from  $\mathcal{H}_0$  by the zero-knowledge property of NIZK.

$\mathcal{H}_2$ : Replace  $Z_i$  with  $Y_i \leftarrow \text{HTLP.Gen}(1 - b)$  and  $\tilde{\pi}$  with  $\tilde{\sigma} \leftarrow \text{NIZK.S}(i, Y_i)$ .  $\mathcal{H}_1$  and  $\mathcal{H}_2$  are indistinguishable because the distributions  $\{Z_i, \mathcal{S}(i, Z_i)\}$  and  $\{Y_i, \mathcal{S}(i, Y_i)\}$  are indistinguishable since  $\{Z_i\}, \{Y_i\}$  are indistinguishable by the security of HTLP.

$\mathcal{H}_3$ : Replace  $\tilde{\sigma}$  with  $\sigma \leftarrow \text{NIZK.Prove}(i, Y_i, 1 - b)$ .  $\mathcal{H}_3$  is indistinguishable from  $\mathcal{H}_2$  by the zero-knowledge property of NIZK.

This series of hybrids implies  $\Pr[b' = b] \approx_\lambda \Pr[b' = 1 - b]$ , where  $b'$  is the output of  $\mathcal{A}$  in  $\mathcal{H}_0$  or  $\mathcal{H}_3$ , respectively. Therefore  $\Pr[\text{ExpSPriv}_{\Pi_\Sigma}^{\mathcal{A}}(\lambda, T, i) = 1] \leq \frac{1}{2} + \text{negl}(\lambda)[\lambda]$ .

Finally, we show that if NIZK is a PoK and HTLP is secure, then Cicada is non-malleable, cf. Definition 13. Suppose towards a contradiction that Cicada is malleable. We will use this and the fact that NIZK is a PoK to construct an adversary  $\mathcal{B}$  which has non-negligible advantage in the HTLP security game. Again, we work in the simple case  $\mathcal{X} = [0, 1]$ , i.e.,  $m, \ell, w = 1$ , but the argument generalizes to other parameter settings.

Since by our assumption Cicada is malleable, there exists  $\mathcal{A}$  which outputs  $(i, \cdot, Z_i, \pi_i) \notin \mathcal{Q}$  such that  $\text{NIZK.Vrfy}((i, Z_i), \pi) = 1$  with non-negligible probability. Given a puzzle  $Z_b$  containing some unknown bit  $b$ ,  $\mathcal{B}$  works as follows. First, it computes  $(\text{pp}, Z) \xleftarrow{\$} \text{Setup}(1^\lambda, T, 1)$  and sends them to the non-malleability adversary  $\mathcal{A}$ .  $\mathcal{B}$  responds to  $\mathcal{A}$ 's oracle queries  $(j, b_j)$  with honestly computed  $(Z_j, \pi_j)$ , keeping track of queries and responses in the set  $\mathcal{Q}$ . When  $\mathcal{A}$  outputs  $(i, Z_i, \pi_i)$ ,  $\mathcal{B}$  looks for  $(i, b_i, Z_i, \pi_i) \in \mathcal{Q}$  and outputs  $b_i$ . Since  $\mathcal{A}$  has non-negligible advantage, it follows that  $\text{NIZK.Vrfy}((i, Z_i), \pi_i) = 1$ . This implies that either  $\Pr[b_i = b] = \frac{1}{2} + \text{negl}(\lambda)[\lambda]$  or NIZK is not knowledge sound. Both possibilities contradict our assumptions, namely that the HTLP is secure and the NIZK is knowledge sound. Thus, Cicada must be non-malleable.  $\square$

## 4.7 Ballot/bid correctness proofs

For our proofs, we assume HTLPs are of the form  $(u, v) = (g^r, h^r y^s) \in \mathbb{G}_1 \times \mathbb{G}_2$ , where  $\mathbb{G}_1, \mathbb{G}_2$  are groups of unknown order. This captures all known constructions of HTLPs: in the case of the Paillier HTLP (Construction 1),  $\mathbb{G}_1 = \mathbb{J}_N$ ,  $\mathbb{G}_2 = \mathbb{Z}_{N^2}^*$ ,  $h = (g^{2^T})^N$ , and  $y = 1 + N$ . For the exponential ElGamal HTLP (Construction 9),  $\mathbb{G}_1 = \mathbb{G}_2 = \mathbb{Z}_N^*$ ,  $h = g^{2^T}$ , and  $y \in \mathbb{G}_1$ . And for the class group HTLP [TCLM21],  $\mathbb{G}_1, \mathbb{G}_2$  are cyclic subgroups of the respective class groups  $Cl(\Delta_K), Cl(q^2 \Delta_K)$ , respectively,  $h = \psi_q(G^{2^T})$  where  $G$  is a generator of  $\mathbb{G}_1$  and  $\psi_q : Cl(\Delta_K) \rightarrow Cl(q^2 \Delta_K)$  is an injective map, and  $y \in \mathbb{G}_2$  is the generator of a subgroup in which the discrete logarithm problem is easy (see [TCLM21] for details).

**Proof of solution.** During the finalization phase of our protocol, any party can solve the final HTLP off-chain and submit a solution to the contract. To enforce the correctness of this solution we require the solver to include a proof

of the following relation:

$$\mathcal{R}_{\text{PoS}} = \{((y, u, v, w \in \mathbb{G}, s \in \mathbb{Z}); \perp) : w = u^{2^T} \wedge v = wy^s \in \mathbb{G}\} \quad (8)$$

We call such a proof system  $\text{PoS} = (\text{Prove}, \text{Verify})$ . It can be realized as the conjunction of two proofs of exponentiation ( $\text{PoE}$ ) [Pie19, Wes19] for  $w = u^{2^T}$  and  $y^s = v/w$ . A  $\text{PoE}$  is a proof for the following relation:

$$\mathcal{R}_{\text{PoE}} = \{((u, w \in \mathbb{G}, x \in \mathbb{Z}); \perp) : w = u^x \in \mathbb{G}\}$$

Note that there is no witness in the  $\mathcal{R}_{\text{PoE}}$  relation, i.e., the verifier knows the exponent  $x$ . The primary goal of the  $\text{PoE}$  proof system for the verifier is to outsource a possibly large exponentiation in a group  $\mathbb{G}$  of unknown order.

**Wesolowski's proof of exponentiation protocol (PoE)**

**Public parameters:**  $\mathbb{G} \xleftarrow{\$} GGen(\lambda)$ .

**Public inputs:**  $u, w \in \mathbb{G}, x \in \mathbb{Z}$ .

**Claim:**  $u^x = w$ .

1.  $\mathcal{V}$  sends  $l \xleftarrow{\$} \text{Primes}(\lambda)$  to  $\mathcal{P}$ .
  2.  $\mathcal{P}$  computes  $q = \lfloor \frac{x}{l} \rfloor \in \mathbb{Z} \wedge r \in [l]$ , where  $x = ql + r$ .  $\mathcal{P}$  sends  $Q = u^q \in \mathbb{G}$  to  $\mathcal{V}$ .
  3.  $\mathcal{V}$  computes  $r = x \bmod l$ .
- $\mathcal{V}$  accepts iff  $w = Q^l u^r$ .

Observe that the verifier sends a prime number as a challenge. When we make this protocol non-interactive via the Fiat-Shamir transform, we use a standard  $\text{HashToPrime}(\cdot)$  function to generate the correct challenge for the prover. In our implementation, we use the Baillie-PSW primality test [PSW80] to show that a randomly hashed challenge is indeed prime.

**Proofs of well-formedness.** To prove that HTLP ballots are well-formed during the submission phase, we will use several different proofs of knowledge about TLP solutions. Most of our protocols make use of the fact that for such HTLPs,  $v$  has the same structure as a Pedersen commitment [Ped92].

Since we are operating in groups of unknown order, to circumvent the impossibility result of [BCK10] and achieve negligible soundness error for Schnorr-style sigma protocols, we assume access to some public element(s) of  $\mathbb{G}_1, \mathbb{G}_2$  whose representations are unknown. We prove security assuming  $\mathbb{G}_1, \mathbb{G}_2$  are generic groups output by some randomized algorithm  $GGen(\lambda)$ . For more on instantiating Schnorr-style protocols in groups of unknown order while maintaining negligible soundness error, see [BBF19].

**Well-formedness and knowledge of solution.** To prove knowledge of a puzzle solution in zero-knowledge, our starting point is the folklore Schnorr-style protocol for knowledge of a Pedersen-committed value. Our protocol zk-PoKS is shown below.

**zkPoK of TLP solution (zk-PoKS)**

**Public parameters:**  $\mathbb{G}_1, \mathbb{G}_2 \xleftarrow{\$} GGen(\lambda)$ ,  $b > 2^{2\lambda}|\mathbb{G}_i| \ \forall i \in \{1, 2\}$ , and  $g \in \mathbb{G}_1, h, y \in \mathbb{G}_2$ .

**Public input:** HTLP  $Z = (u, v)$ .

**Private input:**  $s, r \in \mathbb{Z}$  such that  $Z = (g^r, h^r y^s)$ .

1.  $\mathcal{P}$  samples  $\alpha, \beta \xleftarrow{\$} [-b, b]$  and sends  $A := h^\alpha y^\beta, B := g^\alpha$  to  $\mathcal{V}$ .
2.  $\mathcal{V}$  sends a challenge  $e \xleftarrow{\$} [2^\lambda]$ .
3.  $\mathcal{P}$  computes  $w = re + \alpha$  and  $x = se + \beta$ , which it sends to  $\mathcal{V}$ .

$\mathcal{V}$  accepts iff the following hold:

$$\begin{aligned} v^e A &= h^w y^x \\ u^e B &= g^w \end{aligned}$$

**Equality of solutions.** Again, our starting point is the folklore protocol of equality of Pedersen-committed values: given two HTLPs with second terms  $v_1, v_2$ , if the solutions are equal the quotient is  $v_1/v_2 = h^{r_1-r_2}$ . To prove the equality of the solutions, it therefore suffices to show knowledge of the discrete logarithm of  $v_1/v_2$  with respect to  $h$  using Schnorr's classic sigma protocol [Sch90] with the previously described adjustments. Because of its simplicity we do not explicitly write out the protocol, which we will refer to as zk-PoSEq.

**Binary solution.** In an FFTP vote for  $m = 2$  candidates, users only need to prove that their ballot  $(g^r, h^r y^s)$  encodes 0 or 1. More formally, users prove the statement  $(u = g^r \wedge v = h^r) \vee (u = g^r \wedge v y^{-1} = h^r)$ . This can be proved using the OR-composition [CDS94] of two discrete logarithm equality proofs [CP93] with respect to bases  $g$  and  $h$  and discrete logarithm  $r$ . A similar proof strategy could be applied if the user has multiple binary choices, e.g., approval and range voting. The OR-composition of multiple discrete logarithm equality proofs yields a secure ballot correctness proof for those voting schemes.

**Positive solution.** We use Groth's trick [Gro05], based on the classical Legendre three-square theorem from number theory, to show that a puzzle solution  $s$  is positive by showing that  $4s + 1$  can be written as the sum of three squares. Our protocol deals only with the second component of the TLP, making use of the proof of solution equality (zk-PoSEq) described above and a proof that a TLP solution is the square of another (zk-PoKSqS, described next).

### Proof of positive solution (zk-PoPS)

**Public parameters:**  $\mathbb{G}_2 \xleftarrow{\$} GGen(\lambda)$ , a secure HTLP, and  $h, y \in \mathbb{G}_2$ .

**Public input:**  $v \in \mathbb{G}_2$  such that  $(\cdot, v) \in \text{Im}(\text{HTLP.Gen})$ .

**Private input:**  $s, r \in \mathbb{Z}$  such that  $v = h^r y^s$  and  $s > 0$ .

1. Find three integers  $s_1, s_2, s_3 \in \mathbb{Z}$  such that  $4s + 1 = s_1^2 + s_2^2 + s_3^2$  and, for each  $j = 1, 2, 3$ , compute two HTLPs:

$$Z_j \leftarrow \text{HTLP.Gen}(s_j)$$

$$Z'_j \leftarrow \text{HTLP.Gen}(s_j^2)$$

2. Use zk-PoKSqS to compute a proof  $\sigma_j$  of square solution for each pair  $(Z_j, Z'_j)$  for  $j = 1, 2, 3$ .
3. Use zk-PoSEq to compute a proof  $\sigma_{\text{eq}}$  of solution equality for  $4 \cdot Z \boxplus 1$  and  $Z'_1 \boxplus Z'_2 \boxplus Z'_3$ .

The full proof consists of  $(\sigma_1, \sigma_2, \sigma_3, \sigma_{\text{eq}})$ , all computed with the same challenge  $e \in [2^\lambda]$ .

**Square solution.** To prove that a puzzle solution is the square of another, we use a conjunction of two zk-PoKS variants which proves knowledge of the same solution with respect to different bases. In particular, we consider only the second terms  $v_1 = h^{r_1} y^s$  and  $v_2 = h^{r_2} y^{s^2}$ . We use the fact that  $v_2$  can be rewritten as  $h^{r_2 - r_1 s} v_1^s$  and prove that its opening w.r.t. base  $v_1$  equals the opening of  $v_1$ .

### Proof of square solution (zk-PoKSqS)

**Public parameters:**  $\mathbb{G}_2 \xleftarrow{\$} GGen(\lambda)$ ,  $b > 2^{2\lambda} |\mathbb{G}_2|$ , and  $h, y \in \mathbb{G}_2$ .

**Public input:**  $v_1, v_2 \in \mathbb{G}_2$ .

**Private input:**  $s, r_1, r_2 \in \mathbb{Z}$  such that  $v_1 = h^{r_1} y^s$  and  $v_2 = h^{r_2} y^{s^2} = h^{r_2 - r_1 s} v_1^s$ .

1.  $\mathcal{P}$  samples  $\alpha_1, \alpha_2, \beta \xleftarrow{\$} [-b, b]$  and sends  $A_1 := h^{\alpha_1} y^\beta, A_2 := h^{\alpha_2} v_1^\beta$  to  $\mathcal{V}$ .
2.  $\mathcal{V}$  sends a challenge  $e \xleftarrow{\$} [2^\lambda]$ .
3.  $\mathcal{P}$  computes  $w_1 = r_1 e + \alpha_1, w_2 = (r_2 - r_1 s) e + \alpha_2$ , and  $x = s e + \beta$ , which it sends to  $\mathcal{V}$ .

$\mathcal{V}$  accepts iff the following hold:

$$\begin{aligned} v_1^e A_1 &= h^{w_1} y^x \\ v_2^e A_2 &= h^{w_2} v_1^x \end{aligned}$$

**Quadratic voting [LW18].** Each voter  $i$  submits two linear HTLPs:  $Z_i^{\text{tally}}$  containing  $s_i$  and  $Z_i^{\text{norm}}$  containing  $s_i^2$ , where  $s_i$  is an encoding of the ballot  $\mathbf{b}_i$ .  $Z_i^{\text{tally}}$  will be accumulated into the running tally as usual, and  $Z_i^{\text{norm}}$  will be used to enforce the norm bound. A well-formed sealed ballot is therefore of the form  $Z_i = (Z_i^{\text{tally}}, Z_i^{\text{norm}})$  such that:

**Check #1.** The vector entries enclosed in  $Z_i^{\text{norm}}$  are the squares of those enclosed in  $Z_i^{\text{tally}}$ .

**Check #2.**  $Z_i^{\text{norm}}$  has  $\ell_1$  norm strictly equal to  $w$ .<sup>9</sup>

The first check is much simpler and more efficient when using RNS packing. Recall that with this packing, a solution  $s$  encodes the ballot  $(b_1, \dots, b_m)$  as  $s \bmod p_j \equiv b_j \ \forall j \in [m]$ , and that this encoding is fully SIMD homomorphic. It follows that  $s^2 \bmod p_j \equiv b_j^2$  for all  $j \in [m]$ .<sup>10</sup> With the RNS packing it therefore suffices to prove a square relationship *once* for the puzzles encoding  $s$  and  $s^2$  (e.g., using zk-PoSqs) rather than  $m$  times for all the vector entries. This is in contrast to the PNS packing used by all previous private voting schemes in the literature, where the absence of a multiplicative homomorphism would require proving the square relationship for every vector entry *individually*.

Regardless of the vector encoding, the second check is more involved: the user needs to open a sum of vector entries (the residues) without revealing the entries (residues) themselves. One approach is for the user to commit to each vector entry in  $Z_i^{\text{norm}}$ , i.e.,  $a_{ij} = s_i^2 \bmod p_j$ , with a Pedersen commitment, and use a variant proof of knowledge of exponent modulo  $p_j$  (PoKEMon [BBF19]) to show the commitments contain the appropriate values  $a_{ij}$ . Then, it can open the sum of the commitments. PoKEMon proofs are batchable, so the contract can verify them efficiently and check that the sum of the commitments opens to  $w$ .

**Security proofs.** Finally, we prove special-soundness and honest-verifier zero-knowledge (HVZK) of the above sigma protocols. Any such protocol can be made into a non-interactive zero-knowledge proof of knowledge (NIZKPoK) via the Fiat-Shamir transform [FS87].

**Theorem 3 (zk-PoS).** *The protocol zk-PoS is a special sound and HVZK proof system in the generic group model.*

<sup>9</sup>We make this stricter requirement to simplify the norm check. Note that voters should be incentivized to submit such votes, since it maximizes their voting power.

<sup>10</sup>Assuming  $s_j^2 < p_j$  for all  $j$ , which in our case will hold regardless, we set each  $p_j < nw$  to avoid overflow when adding ballots and  $s_j^2 \leq w < nw$ .

*Proof.* For special soundness, we show that given two distinct accepting transcripts with the same first message, i.e.,  $(A, B, e, w, x)$  and  $(A, B, e', w', x')$  where  $e \neq e'$ , we can extract the witnesses  $r, s$ . The proof follows the blueprint of the proof of Theorem 10 in [BBF19]. Since the transcripts are accepting, we have

$$\begin{aligned} h^w y^x &= v^e A & h^{w'} y^{x'} &= v^{e'} A \\ &= h^{re+\alpha} y^{se+\beta} & &= h^{re'+\alpha} y^{se'+\beta} \end{aligned}$$

Combining the two equations we get

$$\begin{aligned} h^{r\Delta e} y^{s\Delta e} &= h^{\Delta w} y^{\Delta x} \\ \iff v^{\Delta e} &= h^{\Delta w} y^{\Delta x} \end{aligned} \tag{9}$$

where  $\Delta e = e - e'$  and  $\Delta y, \Delta x$  are defined similarly. Then with overwhelming probability,  $r\Delta e = \Delta w$  and  $s\Delta e = \Delta x$  (cf. Lemma 4 of [BBF19]), so  $\Delta e \in \mathbb{Z}$  divides  $\Delta w \in \mathbb{Z}$  and  $\Delta x \in \mathbb{Z}$  and we can extract  $r, s \in \mathbb{Z}$  as  $r = \Delta w / \Delta e$  and  $s = \Delta x / \Delta e$ .

We will now show that these values are correct, i.e.,  $v = h^{\Delta w / \Delta e} y^{\Delta x / \Delta e}$ . Assume towards a contradiction that this does not hold and  $\mu = h^{\Delta w / \Delta e} y^{\Delta x / \Delta e} \neq v$ . Since  $\mu^{\Delta e} = v^{\Delta e}$  by Equation (9), this must mean that  $(\mu/v)^{\Delta e} = 1$  and therefore  $\mu/v \in \mathbb{G}_2$  is an element of order  $\Delta e > 1$ . Since  $\Delta e$  is easy to compute and  $\mu/v$  is a non-identity element of  $\mathbb{G}_2$ , this contradicts the assumption that  $\mathbb{G}_2$  is a generic group (specifically, it contradicts non-trivial order hardness [BBF19, Corollary 2]). We thus conclude that our extractor successfully recovers the witnesses  $r$  and  $s$ .

We still need to verify that the  $r^*$  we can extract from  $u$  will be consistent with the one extracted from  $v$ , i.e.,  $r^* = r$ . Again we know

$$\begin{aligned} g^w &= u^e B & g^{w'} &= u^{e'} B \\ &= g^{r^*e+\alpha^*} & &= g^{r^*e'+\alpha^*} \end{aligned}$$

so by a similar argument  $r^* = \Delta w / \Delta e$ , which equals  $r$ . Thus the protocol satisfies special soundness.

To prove HVZK, we give a simulator which produces an accepting transcript  $(\tilde{A}, \tilde{B}, \tilde{e}, \tilde{w}, \tilde{x})$  that is perfectly indistinguishable from an honest transcript  $(A, B, e, w, x)$ . The simulator is quite simple: it samples  $\tilde{e} \xleftarrow{\$} [2^\lambda]$  identically to an honest verifier, then samples  $\tilde{w}, \tilde{x} \xleftarrow{\$} \mathbb{Z}$  and sets  $\tilde{A} := h^{\tilde{w}} y^{\tilde{x}} v^{-\tilde{e}}$  and  $\tilde{B} := g^{\tilde{w}} u^{-\tilde{e}}$ . It follows by inspection that the transcript is an accepting one. Furthermore, notice that  $\tilde{A}$  and  $\tilde{B}$  are uniformly distributed in  $\mathbb{G}_2$  and  $\mathbb{G}_1$ , respectively, just like  $A, B$  in the honest transcript. Also, both  $\tilde{x}$  and  $x$  are uniform in  $\mathbb{Z}$ . Thus the simulated transcript is perfectly indistinguishable from an honest one.  $\square$

**Theorem 4 (zk-PoSS).** *The protocol zk-PoSS is a special sound and HVZK proof system in the generic group model.*

*Proof.* For special soundness, we show that given two distinct accepting transcripts with the same first message, i.e.,  $(A_1, A_2, e, w_1, w_2, x)$  and  $(A_1, A_2, e', w'_1, w'_2, x')$  where  $e \neq e'$ , we can extract the witnesses  $r_1, r_2, s$ . Notice that  $v_2$  is not guaranteed to encode the square of  $s_1$ , so  $v_2 = h^{r_2 - r_1 s_2 / s_1} v_1^{s_2 / s_1}$ . Let  $\sigma_2 = s_2 / s_1$  and  $\rho_2 := r_2 - r_1 s_2 / s_1 = r_2 - r_2 \sigma_2$ .

Using the same extractor as in the proof of Theorem 3, we can extract correct integers  $r_1 = \Delta w_1 / \Delta e$ ,  $s_1 = \Delta x / \Delta e$ ,  $\rho_2 = \Delta w_2 / \Delta e$ , and  $\sigma_2 = \Delta x / \Delta e$ . Notice  $s_1 = \sigma_2$ , which implies  $\sigma_2 = s_1^2$ . Finally we use  $r_1, s_1, \rho_2 \in \mathbb{Z}$  to recover  $r_2 := \rho_2 + r_1 s_1 \in \mathbb{Z}$ . Thus the protocol is special sound.

To prove HVZK, we give a simulator which produces an accepting transcript  $(\tilde{A}_1, \tilde{A}_2, \tilde{e}, \tilde{w}_1, \tilde{w}_2, \tilde{x})$  that is perfectly indistinguishable from an honest transcript  $(A_1, A_2, e, w_1, w_2, x)$ . The simulator is quite simple: it samples  $\tilde{e} \xleftarrow{\$} [2^\lambda]$  identically to an honest verifier, then samples  $\tilde{w}_1, \tilde{w}_2, \tilde{x} \xleftarrow{\$} \mathbb{Z}$  and sets  $\tilde{A}_1 := h^{\tilde{w}_1} y^{\tilde{x}} v_1^{-\tilde{e}}$  and  $\tilde{A}_2 := h^{\tilde{w}_2} v_1^{\tilde{x}} v_2^{-\tilde{e}}$ . It follows by inspection that the transcript is an accepting one. Furthermore, notice that  $\tilde{A}_1, \tilde{A}_2$  are uniformly distributed in  $\mathbb{G}_2$ , respectively, just like  $A_1, A_2$  in the honest transcript. Also, both  $\tilde{w}_1, \tilde{w}_2, \tilde{x}$  are uniform in  $\mathbb{Z}$  just like  $w_1, w_2, x$ . Thus the simulated transcript is perfectly indistinguishable from an honest one.  $\square$

**Theorem 5 (zk-PoPS).** *The protocol zk-PoPS is sound and HVZK.*

*Proof.* Soundness follows directly from the (knowledge) soundness of zk-PoKSqS and zk-PoSEq as well as Legendre's three-square theorem [Gro05].

For HVZK, note that an honest zk-PoPS transcript has the form  $(\{A_{1,j}, A_{2,j}\}_{j \in [3]}, R, e, \{w_{1,j}, w_{2,j}, x_j\}_{j \in [3]})$ , where  $(R, e, x)$  is an honest zk-PoSEq transcript and  $(A_{1,j}, A_{2,j}, e, w_{1,j}, w_{2,j}, x_j)$  for  $j = 1, 2, 3$  are honest zk-PoKSqS transcripts. Given the instance  $v$ , our zk-PoPS simulator first computes some random HTLPs  $(\tilde{u}_j, \tilde{v}_j), (\tilde{u}'_j, \tilde{v}'_j) \xleftarrow{\$} \text{HTLP.Gen}(0)$  for  $j = 1, 2, 3$ . These simulated underlying instances are indistinguishable from the honest instances an honest prover would use. This follows from the security of HTLP.

Next, our simulator samples  $\tilde{e} \xleftarrow{\$} [2^\lambda]$  identically to an honest verifier and uses the simulators of the proof systems, always with the same challenge  $\tilde{e}$ , to produce a simulated transcript:

$$\begin{aligned} (\tilde{A}_{1,j}, \tilde{A}_{2,j}, \tilde{e}, \tilde{w}_{1,j}, \tilde{w}_{2,j}, \tilde{x}_j) &\leftarrow \mathcal{S}_{\text{zk-PoKSqS}}(\tilde{v}_j, \tilde{v}'_j; \tilde{e}) \quad \forall j = 1, 2, 3 \\ (\tilde{R}, \tilde{e}, \tilde{x}) &\leftarrow \mathcal{S}_{\text{zk-PoSEq}}\left(\frac{4 \cdot v \boxplus 1}{\tilde{v}'_1 \boxplus \tilde{v}'_2 \boxplus \tilde{v}'_3}; \tilde{e}\right) \end{aligned}$$

By HVZK of zk-PoKSqS and zk-PoSEq, these transcripts are accepting and indistinguishable from an honestly generated transcript.  $\square$

## 4.8 Parameter Settings

In this section, we evaluate the practicality and optimality of various HTLP constructions based on the parameters  $M, n, m, w$  of the auction or vote. Assuming

the classic PNS packing, we require  $(nw + 1)^m \leq |\mathbb{G}|$  for voting and  $M^n \leq |\mathbb{G}|$  for auctions, where  $\mathbb{G}$  is the group in which the HTLP is instantiated. We show the optimal HTLP construction for auctions and voting for various parameter settings in Figure 6 (with packing) and Figure 7 (without packing). We use the security parameter  $\lambda = 80$  (see discussion in Section 4.9), which corresponds to a 1024-bit modulus  $N$  for exponential ElGamal and Paillier HTLPs and 3400-bit discriminants for class group HTLPs. For the exponential ElGamal HTLP, we fixed the maximum ballot at  $2^{80}$ , which corresponds to  $\approx 2^{40}$  brute-forcing work using Pollard’s rho algorithm [Pol78].

**Exponential ElGamal HTLP (Construction 9)** This is the most efficient HTLP construction: for a given security parameter, it has the smallest required cryptographic groups and most efficient group operations. However, since the puzzle solution is encoded in the exponent, solving the puzzle requires brute-forcing a discrete logarithm. This limits the use of this construction to a small set of parameter settings: assuming the largest discrete logarithm an off-chain solver can be expected to brute-force has  $\tau$  bits, we require  $(nw + 1)^m \leq 2^{2\tau}$ .

**Paillier HTLP (Construction 1)** This is a slightly less efficient construction since the size of the HTLPs for a given security parameter is doubled due to working over  $\text{mod } N^2$  instead of  $\text{mod } N$ . This increases both the required storage and the complexity of the group operation. On the other hand, due to its larger solution space, the Paillier HTLP supports much broader parameter settings for a given security parameter.

**Class group HTLP** Class group offer the sole HTLP construction without a trusted setup [TCLM21]. This comes at the cost of the largest groups for a given security parameter. Class groups are not widely supported by major cryptographic libraries, and their costly group operation makes blockchain deployment difficult. We are unaware of any class group implementations for Ethereum smart contracts.

**Impractical parameter settings** Accommodating very large settings of  $n, w, m, M$  requires larger groups, leading to group operations and storage requirements which are intolerably inefficient for certain applications.

## 4.9 Implementation

We implemented our transparent on-chain coordinator as an Ethereum smart contract in Solidity.<sup>11</sup> For efficiency, we use the exponential ElGamal HTLP with a 1024-bit modulus  $N$ . To enable 1024-bit modular arithmetic in  $\mathbb{Z}_N^*$ , we developed a Solidity library which may be of independent interest. This size of  $N$  corresponds to approximately  $\lambda = 80$  bits of security. Although this security level is no longer deemed cryptographically safe, the secrecy of the

<sup>11</sup>Open-sourced at <https://github.com/a16z/cicada>.

HTLP solutions is only guaranteed up to time  $T$  regardless, so this security level will suffice for our use case as long as the best-known factoring attack takes at least  $T$  time. A 2012 estimate for factoring 1024-bit integers is about a year [BHL12], which is significantly longer than the typical submission period of a decentralized auction or election.

The main factors influencing gas cost (see ??) are submission size, correctness proof size, and verification complexity. These factors mainly depend on the packing parameter  $\ell \in [m]$ , which determines a storage-computation trade-off with the following extremes:

**One aggregate HTLP for all.** If  $\ell = m$ , the contract maintains a single aggregate HTLP  $Z$ . This greatly reduces the on-chain space requirements of the resulting voting or auction scheme at the expense of typically more complex and larger submission correctness proofs.

**One aggregate HTLP per candidate.** If  $\ell = 1$ , the contract must maintain  $m$  aggregate HTLPs  $\{Z_j\}_{j \in [m]}$ . This increases the on-chain storage, but the submissions of correctness proofs become smaller and cheaper to verify.

In ??, we empirically explore this trade-off space by measuring the gas costs of various deployments of our framework with a range of parameter settings  $M, n, m, w, \ell$ .

First, we briefly describe the proof systems used for each scheme we implement; detailed descriptions are given in ??.

**Binary voting.** In a binary vote (i.e., approval voting with  $m = 1$ ), such as a simple yes/no referendum, users prove that the submitted ballot  $Z = (u, v)$  is an exponential ElGamal HTLP with solution 0 or 1:  $(u = g^r \wedge v = h^r) \vee (u = g^r \wedge v y^{-1} = h^r)$ . This is achieved via OR-composition [CDS94] of two sigma protocols for discrete logarithm equality [CP93].

**Cumulative voting.** In cumulative voting, each user distributes  $w$  votes among  $m$  candidates. To accommodate a larger number of candidates, our implementation keeps  $m$  tally HTLPs  $Z_j$ , one for each candidate (in other words,  $\ell = 1$ ). Each voter  $i$  submits  $m$  ballots  $Z_{ij} = (g^{r_{ij}}, h^{r_{ij}} y^{s_{ij}})$  for all  $j \in [m]$ . Besides proving (using the protocol zk-PoKS) that each HTLP is well-formed (the same  $r_{ij}$  is used in both terms), the voter must prove that  $0 \leq s_{ij} \forall j \in [m]$  and  $\sum_{j=1}^m s_{ij} = w$ . The first condition is shown with a proof of positive solution (zk-PoPS) via Legendre’s three-square decomposition theorem [Gro05]. As a building block, we use a proof of square solution (zk-PoKSqS) to show that a puzzle solution is a square. The second condition is proven by providing the randomness  $R_i = \prod_j r_{ij}$  which opens  $\prod_j Z_{ij}$  to  $w$ .

**Sealed-bid auction.** To illustrate two extremes of the packing spectrum, we implement two flavors of sealed-bid auctions. The first uses a single aggregate HTLP as described in ?? (this can be viewed as  $\ell = b$ , where  $b = \lceil \log_2(M) \rceil$

Binary vote		Cumulative vote ( $\ell = 1$ )				
$m$	1	2	3	4	5	6
Aggr	418,358	3,391,514	5,081,542	6,781,389	8,489,786	10,208,185
Finalize	115,690	269,505	397,789	521,895	644,814	770,934

Finalize	147,634	1,005,208	1,253,119	1,497,760	1,749,489	2,003,282

Table 5: Gas costs for Cicada cumulative voting and sealed-bid auctions with various numbers of candidates  $m$ , bid bit-lengths  $b$  (max. bid  $M = 2^{b-1}$ ), and packing parameters  $\ell$ .

is the bit-length of a bid): Bidder  $i$  submits a single HTLP  $Z_i = (g^{r_i}, h^{r_i} y^{s_i})$ , proving well-formedness with zk-PoKS and two zk-PoPS to show  $0 \leq s \leq M$ . The coordinator aggregates the  $i$ th bidder’s bid by adding  $M^{i-1} \cdot Z_i$  to its tally.

The second approach applies  $b$  aggregate HTLPs (i.e.,  $\ell = 1$ ): Each bidder  $i$  submits  $b$  HTLPs  $\{Z_{ij}\}_{j \in [b]}$  and uses the same proof system as in binary voting to prove their well-formedness, i.e., the user inserted for each bit of the bid 0 or 1. The coordinator adds  $2^i \cdot Z_{ij}$  to each corresponding aggregate HTLP  $Z_j$ .

**Submission costs.** The on-chain cost of submitting a bid/ballot is the cost of running the **Aggr** function by the contract, i.e., the verification of the well-formedness proofs plus adding the users’ submissions to the tally HTLPs (if and only if they verify). We report our measurements without packing (i.e.,  $\ell = 1$ ) in Table 5. Submitting a binary vote ballot costs 418,358 gas ( $\approx 11.02$  USD on Ethereum).<sup>12</sup> For cumulative voting, the submission cost scales linearly in  $m$ : with  $m = 2$  candidates, submitting a ballot costs 3,391,514 gas ( $\approx 94.49$  USD), and each additional candidate adds  $\approx 1,699,847$  gas ( $\approx 44.79$  USD).

An auction with a single HTLP for each bit of the bid (the  $\ell = 1$  case) requires a submission cost of 3,586,022 gas ( $\approx 94.49$  USD) for an 8-bit bid. Every additional bit in the submitted bid burns  $\approx 451,014$  gas ( $\approx 11.89$  USD). On the other hand, if one applies packing, i.e.,  $\ell = b$ , then the cost of submitting a sealed bid is constant at 3,055,107 gas ( $\approx 80.50$  USD). As seen in Table 5, with bid-space  $M = 2^7$  it is already more economical to have a single aggregate HTLP and use a packing scheme, despite more complex bid-correctness proofs.

**Finalization costs.** Our voting and auction schemes end with solving the tally HTLP(s) off-chain, i.e., computing  $(g^r)^{2^T} (= h^r)$ . With exponential ElGamal, solving the puzzle also requires a brute-force discrete logarithm computa-

<sup>12</sup>We can estimate gas costs for approval voting using the cost of binary voting, as the former uses a disjunction of  $m$  copies of the same NIZK and thus scales linearly.

tion by the off-chain solver. The correctness of this computation is proven to the contract with Wesolowski’s PoE [Wes19] (recalled in ??). The Finalize cost comes from verifying the PoE(s) on-chain, which burns 101,066 gas ( $\approx 2.66$  USD) per proof. Without packing, the untrusted solver must provide a Wesolowski proof per tally HTLP, so the Finalize gas cost is linear in the number of tally HTLPs, as evidenced by Table 5. A portion of the Wesolowski verification cost comes from checking that the challenge is a prime number. In our implementation, the prover provides a Baillie-PSW [PSW80] primality certificate, whose verification cost is 44,972 gas ( $\approx 1.18$  USD).

**Verification costs.** We implemented the sigma protocols described in ?? in Solidity and report their verification costs in Table 6. With Groth’s trick [Gro05] in the proof of positivity (zk-PoPS), we must decompose the integer solution into the sum of only three squares. Therefore, the gas cost of verifying zk-PoPS equals the cost of verifying three proofs of knowledge of square solutions (zk-PoKSqS) and one proof of knowledge of equal solution (zk-PoSEq).

Sigma protocol	Verification gas cost
Proof of Exponentiation (PoE [Wes19])	101,066
PoK of solution (zk-PoKS)	266,096
Proof of solution equality (zk-PoSEq)	336,155
Proof of square solution (zk-PoKSqS)	336,168
Proof of positive solution (zk-PoPS)	1,351,958

Table 6: EVM gas costs of verification for the proof systems described in ??.

In the short-term, deploying on Layer 2 (L2) already brings these costs down by 1–2 orders of magnitude. For example, when deploying our implementation on the Optimism L2 rollup, casting a binary vote would cost less than 0.30 USD. Further optimizations (e.g., Karatsuba multiplication [KO62], batched Wesolowski proof verification [Rot21], or verification via efficient zkSNARKs [Gro16, GWC19]) can bring the costs down even more.

## 4.10 Extensions

We introduce extensions to the Cicada framework that may be useful in future applications.

### 4.10.1 Everlasting ballot privacy for HTLP-based protocols

**Noemi:** Note this introduces interactivity but off-chain

The basic Cicada framework does not guarantee long-term ballot privacy. Submissions are public after the Open stage. This is because users publish their HTLPs on-chain: once public, the votes contained in the HTLPs are only

guaranteed to be hidden for the time it takes to compute  $T$  sequential steps, after which point it is plausible that someone has computed the solution. In many applications, it is desirable that individual ballots remain hidden *even after voting has ended* since the lack of everlasting privacy may facilitate coercion and vote-buying. As mentioned in Section 4.5, this can be achieved modularly by first decoupling the ballots from their voters via a privacy-enhancing overlay. Alternatively, we describe how the Seal procedure can be modified to prevent the opening of individual ballots, achieving everlasting privacy.

Observe that all known *efficient HTLP constructions* are of the form  $(u, v) = (g^r, h^{r^T} X)$ ,<sup>13</sup> where the solution is encoded in  $X$  and recovering it requires recomputing  $h^r = (g^r)^{2^T}$  via repeated squaring of the first component. Our insight is that the puzzle information-theoretically hides the solution  $X$  without the first component. Importantly, publishing  $g^r$  is not necessary in any of our HTLP-based voting protocols *except as a means to verifiably compute the first component of the final HTLP*, i.e.,  $g^R = g^{\sum_{i \in [n]} r_i}$ . The observation that  $g^R$  can be computed *without* revealing the individual values  $g^{r_i}$  enables us to construct the first practical and private voting protocols that guarantee *everlasting* ballot privacy with a single on-chain round.

For simplicity, consider a protocol in which both the ballot of user  $i$  and the tally consists of a single HTLP, respectively  $Z_i = (g^{r_i}, h^{r_i} X_i)$  and  $Z = (g^R, h^R X)$ . Observe that for everlasting ballot privacy, updates to  $Z$  must inherently be batched: a singleton update  $\text{Aggr}(\text{pp}, Z, Z_i, \pi) \rightarrow (g^{R+r_i}, h^{R+r_i} Y)$  (for some  $Y$ ) would reveal  $g^{r_i} = g^{R+r_i} / g^R$ , which is the opening information to  $Z_i$ , as the quotient of the first component of  $Z$  after and before the update. Hence, the ballot  $X_i$  of user  $i$  would be recoverable in  $T$  sequential steps, i.e., after computing  $h^{r_i} = (g^{r_i})^{2^T}$ .

Batching ballot submissions off-chain in groups of  $k$  allows parties to achieve everlasting privacy as long as at least one party is honest. The parties aggregate their submissions off-chain as  $(g^R, h^R X) = (\prod_i g^{r_i}, \prod_i h^{r_i} X_i)$  and compute a proof  $\pi_{\text{batch}}$  of well-formedness in a distributed-prover zero-knowledge proof protocol [DPP<sup>+</sup>22]. We use the observation that the individual second components  $v_i$  are hiding to optimize the batching by computing  $h^R X$  in the clear (see Figure 8 for details).

This idea opens up a new design space for the MPC protocol used for batching, such as doing the randomness generation in a preprocessing phase instead, allowing dynamic additions to the anonymity set, optimizing the batch proof generation, and dealing with parties who fail to submit. We leave the full exploration of this large design space and related questions to future work.

#### 4.10.2 Succinct ballot-correctness proofs

Real-world elections often have hundreds of candidates, e.g., Optimism’s retroactive public good funding [Opt]. However, the state-of-the-art ballot correctness

<sup>13</sup>In the exponential ElGamal case,  $h' = h$ , while in the Paillier construction,  $h' = h^N$  (see Section 2.3). We will drop the tickmark on  $h'$  in the remainder of this section to avoid notational clutter.

proofs [BBC<sup>+</sup>23, Gro05] for all voting schemes (e.g., FPTP, approval voting, etc.) are linear in the number of candidates, rendering these schemes impractical in the blockchain setting. To counter these issues, we design constant-size ballot correctness proofs with constant verification time at the expense of an added preprocessing phase. The high-level idea is as follows. All correct ballots (e.g.,  $\{\text{Pack}(s) : s \in \{0, 1\}^m\}$  in the case of approval voting) are inserted into an accumulator or polynomial commitment (PC) [KZG10] during a transparent preprocessing phase. When users submit their votes  $Z \xleftarrow{\$} \text{HTLP.Gen}(s)$ , they prove in zero-knowledge that  $Z$  encodes a correct ballot, i.e., the users show that the solution  $s$  of  $Z$  had been previously inserted into the accumulator or PC with a succinct (blinded) membership proof [ZBK<sup>+</sup>22].

In this section, we assume that a common reference string for the KZG polynomial commitment (PC) scheme [KZG10] is already available to users, namely  $\text{crs} := \{g_1^{\tau^j}\}_{j=1}^d$ , where  $g_1 \in \mathbb{G}_1$  is a generator in a bilinear pairing-friendly cyclic group  $\mathbb{G}_1$  over  $\mathbb{F}_p$  for some prime  $p$ ,  $\tau \xleftarrow{\$} \mathbb{F}_p$  hidden to everyone. The  $\text{crs}$  is typically established during a sequential, secure multi-party computation (MPC), e.g., [BGG19].

Let us assume that users have established during a preprocessing phase (Figure 9) a short commitment  $\text{com}$  that encodes all the possible ballots in a particular voting scheme, e.g.,  $\mathcal{X} = [0, 1]^m$  for approval voting. The size of classical proofs of well-formedness, e.g., OR-composition of sigma-protocols, scale linearly in the number of candidates  $m$ . The following proof strategy yields a constant-size proof of correctness for moderately-sized  $\mathcal{X}$ , i.e.,  $|\mathcal{X}| \leq d^{14}$ .

First, given a ballot  $Z = (g^r, h^r y^s) \in \tilde{\mathbb{G}}_1 \times \tilde{\mathbb{G}}_2$ , the user creates an elliptic curve point  $Z_1 = h_1^r y_1^s \in \mathbb{G}_1$  for random generators  $h_1, y_1 \xleftarrow{\$} \mathbb{G}_1$  in a pairing-friendly group. Using the discrete logarithm across different groups techniques developed in [COPZ22], the user can show that  $Z$  and  $Z_1$  have the same discrete logarithms  $r$  and  $s$  with for their bases  $h, y \in \mathbb{G}, h_1, y_1 \in \mathbb{G}_1$ , respectively. Now that  $Z_1$  and the polynomial commitment are in the same pairing-friendly group  $\mathbb{G}_1$ , the user can create a blinded KZG opening proof [ZBK<sup>+</sup>22] to prove ballot correctness. Specifically, the proof  $\pi$  shows that the value  $s$  in  $Z_1$  matches an evaluation of the polynomial  $f$  committed by  $\text{com}$  at some (hidden) point  $j$ , i.e.,  $f(j) = s$ . Note that the verifier only sees constant-size commitments of  $f, j$ , and  $s$ . Since the blinded KZG proof  $\pi$  is also constant-size, this strategy yields the first succinct ballot-correctness proofs for many common voting schemes, e.g., approval and range voting.

#### 4.10.3 Coercion-Resistance

Lastly, we briefly outline how one could add coercion-resistance [JCJ05] to our framework. In the e-voting literature, there are two main pathways to obtaining coercion-resistance: receipt-freeness or allowing unlikable revotes. Receipt-freeness seems challenging to achieve in the blockchain context, and we leave

<sup>14</sup>The largest KZG CRS we know of [Prib] is for  $d = 2^{28}$ , so in the case of  $\mathcal{X} = [0, 1]^m$  this strategy requires  $m \leq 28$ .

it to future work. Therefore, we follow the revoting paradigm akin to Lueks et al. [LQT20]. One can allow indistinguishable revotes as follows. We could store our ballots in a zero-knowledge set (e.g., Semaphore is a readily available implementation of this concept for Ethereum [Eth19]). Additionally, we would need to store a Merkle tree of nullifiers on-chain containing the ballots that are revoked due to revoting. Whenever users want to revoke, they could prove in zero-knowledge that they revoke a previous ballot that they inserted in the zero-knowledge set while they reveal the accompanying nullifier and insert it into the nullifier tree. We leave it to future work to flesh out the technical details and implementation of such an extension.

#### 4.10.4 Bayesian truth serum

Bayesian truth serum [Pre04] is a method for eliciting truthful subjective answers where objective truth does not exist or is not knowable. The core of the idea is to reward answers that are “surprisingly common” by leveraging respondents’ own predictions of what will be common. Thus, for a question with many (mutually exclusive) potential answers, the score of user  $i$  responding  $\mathbf{x}_i := (x_{i1}, \dots, x_{im})$  and  $\mathbf{y}_i := (y_{i1}, \dots, y_{im})$  is calculated as

$$\text{score}_i := \sum_{j \in [m]} x_{ij} \log \frac{\bar{x}_j}{\bar{y}_j} + \alpha \sum_{j \in [m]} \bar{x}_j \log \frac{y_{ij}}{\bar{x}_j} \quad (10)$$

where  $\alpha > 0$  is a constant. The variable  $x_{ij} \in \{0, 1\}$  denotes user  $i$ ’s decision (choose or don’t choose) for option  $j \in [m]$ ,  $\bar{x}_j$  is the empirical frequency of choice  $j$  over all the users’ answers,  $y_{ij}$  is user  $i$ ’s estimate of  $\bar{x}_j$  (i.e., their estimate of the probability of answer  $j$  among all users), and  $\bar{y}_j$  is the empirical (geometric) average of  $y_{ij}$  over all the users’ answers. Since each user can only choose a single answer,  $x_{ij}$  will be 0 for all but one value of  $j$ , which we denote  $j^*$ . Thus, we can think of the equation above as equivalent to

$$x_{ij^*} \log \frac{\bar{x}_{j^*}}{\bar{y}_{j^*}} + \alpha \sum_{j \in [m]} \bar{x}_j \log \frac{y_{ij}}{\bar{x}_j}.$$

The first term is referred to as the *information score* and the second as the *prediction score*. The information score is highest when the user’s choice  $k^*$  is “surprisingly common”, i.e., when the empirical frequency of answer  $j^*$  ( $\bar{x}_{j^*}$ ) is higher than the crowd’s estimate of the empirical frequency of  $j^*$  ( $\bar{y}_{j^*}$ ). Therefore participants are incentivized to submit their truthful responses, even (and especially) if they believe them to be uncommon.

The prediction score is the Kullback-Leibler divergence [KL51] between the user’s estimate of the average answer and the true average answer, weighted by  $\alpha$ . This is maximized when the two values are equal (i.e., the divergence is 0), and so incentivizes truthful reporting of  $y_{ij}$ , the user’s estimate of  $\bar{x}_j$ .

We show how Bayesian truth serum can be implemented in the Cicada frame-

work. First, rewrite Equation (10) as

$$\text{score}_i := \sum_{j \in [m]} x_{ij}(\log \bar{x}_j - \bar{y}'_j) + \alpha \sum_{j \in [m]} \bar{x}_j(y'_{ij} - \log \bar{x}_j) \quad (11)$$

where  $y'_{ij} = \log y_{ij}$  and  $\bar{y}'_j = \log \bar{y}_j$ . The smart contract will use two (lists of) HTLPs  $\mathcal{Z}_{\bar{\mathbf{x}}}^{\text{tally}}, \mathcal{Z}_{\bar{\mathbf{y}}'}^{\text{tally}}$  to keep track of two running “tallies”:

$$\begin{aligned} \bar{\mathbf{x}} &= (\bar{x}_1, \dots, \bar{x}_m) = \sum_i \mathbf{x}_i \\ \bar{\mathbf{y}}' &= (\bar{y}'_1, \dots, \bar{y}'_m) = \sum_i \frac{1}{n} \mathbf{y}'_i \end{aligned}$$

Each user’s ballot consists of the vectors  $\mathbf{x}_i, \mathbf{y}'_i$ , where  $\mathbf{x}_i \in [0, 1]^m$  has  $\ell_1$  norm 1 and  $\mathbf{y}'_i = \log \mathbf{y}_i \in \mathbb{N}^m$  with  $\sum_{j \in [m]} y_{ij} = n$ . Assuming no packing for simplicity, the ballot is encoded as three lists of HTLPs: a list of linear HTLPs  $\mathcal{Z}_i^{\text{ans}} := \{Z_{ij}^{\text{ans}}\}_{j \in [m]}$  for the entries of  $\mathbf{x}_i$ , and two lists of (respectively) linear and multiplicative HTLPs  $\mathcal{Z}_i^+ := \{Z_{ij}^+\}_{j \in [m]}$  and  $\mathcal{Z}_i^\times := \{Z_{ij}^\times\}_{j \in [m]}$ , both encoding the entries of  $\mathbf{y}'_i$ . The smart contract coordinator must ensure that the following hold:

**Check #1a.** All  $Z_{ij}^{\text{ans}}$  encode  $x_{ij} \in [0, 1]$ .

**Check #1b.**  $\sum_{j \in [m]} x_{ij} = 1$ .

**Check #2a.** All  $Z_{ij}^+$  encode  $y'_{ij} > 0$ .

**Check #2b.**  $\sum_{j \in [m]} 2^{y'_{ij}} = n$  (assuming log base 2).

**Check #3.**  $\mathcal{Z}_i^\times$  contains the same value as  $\mathcal{Z}_i^+$  for all  $j \in [m]$ .

Most of these checks can be achieved using the protocols in Section 4.7: Check #1a with the binary solution protocol, #1b and #2b by providing randomness which opens the homomorphic sum to the correct value, and #2a with zk-PoPS. Check #2b additionally requires a zero-knowledge proof of exponentiation, e.g., [BBF19]. Because the puzzles to check in #3 use different constructions, we can’t apply zk-PoSEq directly; instead, one can combine two zk-PoKS proofs with a standard PoK for discrete logarithm.

The aggregation algorithm  $\text{Aggr}((\mathcal{Z}_{\bar{\mathbf{x}}}^{\text{tally}}, \mathcal{Z}_{\bar{\mathbf{y}}'}^{\text{tally}}), i, \mathcal{Z}_i, \pi_i)$  updates the tally to  $(\mathcal{Z}_{\bar{\mathbf{x}}}^{\text{tally}} \boxplus \mathcal{Z}_i^{\text{ans}}, \mathcal{Z}_{\bar{\mathbf{y}}'}^{\text{tally}} \boxplus \frac{1}{n} \cdot \mathcal{Z}_i^+)$ . During the opening phase, anyone can solve for the final tallies  $\bar{\mathbf{x}}_{\text{final}}, \bar{\mathbf{y}}'_{\text{final}}$  and the individual user submissions  $\{(\mathbf{x}_i, \mathbf{y}'_i)\}_{i \in [n]}$ . If correct, they are used in **Finalize** to compute the final set of scores as follows:

1. Let  $\bar{\mathbf{x}}' := \log \bar{\mathbf{x}}$ . Compute  $\mathbf{I}' := \bar{\mathbf{x}}' - \bar{\mathbf{y}}'$  and  $\mathbf{P}' := \bar{\mathbf{x}} \cdot \bar{\mathbf{x}}'$ .
2. For each user  $i \in [n]$ :

- (a) Compute  $i$ 's information score  $I_i := \sum_{j \in [m]} I_{ij}$ , where  $\mathbf{I}_i = (I_{i1}, \dots, I_{im}) := \mathbf{x}_i \cdot \mathbf{I}'$ .
- (b) Compute  $i$ 's prediction score  $P_i := \sum_{j \in [m]} P_{ij}$ , where  $\mathbf{P}_i = (P_{i1}, \dots, P_{im}) := \bar{\mathbf{x}} \cdot \mathbf{y}'_i - \mathbf{P}'$ .
- (c) User  $i$ 's score is  $I_i - P_i$ .

#### 4.10.5 A trusted setup protocol for the CJSS scheme

Chvojka, Jager, Slamanig, and Striecks [CJSS21] describe how to combine a public-key encryption scheme with a TLP to obtain a private voting or auction protocols which, unlike the HTLP-based approach suggested by [MT19], is “solve one, get many for free”. The high-level idea of the protocol is to encrypt each user’s bid with a common public key whose corresponding secret key is inserted into a TLP (see Figure 10). Therefore, none of the bids can be decrypted until the corresponding encryption secret key is obtained by solving the TLP. One drawback of this scheme, however, is that it requires an additional trusted setup procedure to create a TLP containing the secret key corresponding to the encryption public key used. Furthermore, unlike the HTLP approach, the setup cannot be reused and must be re-run for every protocol invocation.

We observe that, for encryption schemes with discrete-log key-pairs such as Cramer-Shoup [CS98], there is a natural decentralized setup protocol secure against all-but-one corruptions. Using the blockchain as a broadcast channel (similar to [NRBB24]), a simple sequential MPC protocol to set up the parameters works as follows. Suppose there is some smart contract that stores the public key  $\mathbf{pk} = g^{\mathbf{sk}} \bmod N$  and a TLP  $Z_{\mathbf{sk}}$  containing  $\mathbf{sk}$  (initially, one can set  $\mathbf{sk} = 0$ ). Each contributor  $i$  can update  $\mathbf{pk}$  by adding  $s_i$  homomorphically in the exponent and contributing an HTLP  $Z_i = (g^{r_i} \bmod N, h^{r_i \cdot N} \cdot (1 + N)^{s_i})$ . The contribution must be accompanied by a proof of well-formedness. For the previous state  $\mathbf{pk}, Z_{\mathbf{sk}}$ , contributor  $i$  proves that its contribution  $\mathbf{pk}_i, Z_i$  passes the following checks:

**Check #1.** It knows the discrete logarithm of  $\mathbf{pk}_i$  with respect to the base  $g$ . This can be achieved with a proof of knowledge of the exponent [Sch90].

**Check #2.** It knows the representation of the HTLP contribution  $Z_i$  with respect to the bases  $g, h^N, (1 + N)$  (i.e., the discrete logarithms  $r_i, r_i, s_i$ ). This can be proven by a “knowledge of representation” proof system in groups of unknown order (e.g., [BBF19]).

**Check #3.** Finally, the discrete logarithms  $a, b, c$  from check #2 are such that  $a = b$  and  $c = \text{dlog}_g(\mathbf{pk}_i)$ .

The state is updated with the  $i$ th contribution iff all the checks pass. After the update,  $Z_{\mathbf{sk}} := Z_{\mathbf{sk}} \cdot Z_i$  and  $\mathbf{pk} := \mathbf{pk} \cdot \mathbf{pk}_i = g^{s + s_i}$ . A single honest contributor suffices to guarantee a uniformly distributed keypair.

## 5 Hot-Cold Threshold Wallets

*(Parts of this section are taken/adapted from [GGJ<sup>+</sup>24].)* In the cryptocurrency ecosystem, anyone who controls the signing key for some account can take actions on the user’s behalf. This makes signing keys very valuable cryptographic material, since they can allow an attacker to transfer potentially large sums of money out of a user’s account with no recourse. A plethora of solutions has emerged to safeguard these keys in the form of cryptocurrency wallets.

Wallets can be classified into two types: custodial and non-custodial solutions. In a custodial wallet, a client trusts some third party (the custodian) to store the signing key on their behalf and use it to authorize transactions at their request. This clearly requires a strong trust assumption but relieves the client of the need to securely store such a high-value secret. At the other end of the spectrum, non-custodial wallets require clients to store their own signing keys, e.g., on their machine or in a hardware wallet [AGKK19]. This can be a usability issue, since by definition there cannot be a recovery or reset mechanism in case the client loses the key file or hardware wallet, or if the key material is compromised. An increasingly common compromise between these two extremes are threshold wallets [KMOS21, DEF<sup>+</sup>23, BMP22, Eya21]. These are essentially custodial wallets with multiple custodians, where each one is given only a share of the signing key. This maintains the usability advantages of custodial wallets while reducing the trust placed in any single custodian. Unfortunately, the normally highly-interactive threshold signing procedures require custodians to be online during the signing phase, making them vulnerable to attacks aiming to learn their shares [NNN<sup>+</sup>23, Mak23].

**Cold wallets** A common mitigation is to keep only limited funds in the online wallet, with most of a user’s assets kept in a highly secure air-gapped wallet. This can be realized via, e.g., a deterministic wallet [But13, DFL19, ADE<sup>+</sup>20, Hu23, ER22], which enables unlinkable transfers to an offline wallet by specifying how to deterministically derive session keys from a master public-private key pair. Thus, the online wallet can compute and publish the current session public key, allowing anyone to transfer money to the cold wallet (which can derive the corresponding session private key).

This idea is standardized by the BIP32 proposal [Wui12], which also defines how these session keys can be derived in a hierarchical manner to create “child” wallets who can control their own funds. Because the master secret key (and any session/child secret keys) must still be stored in a trusted place, this makes the offline wallet a highly valuable target when it inevitably comes online to transfer funds to the online wallet. Although a recent work [DEF<sup>+</sup>23] shows how to enable threshold child wallets, the issue of a single point of failure still persists at the root wallet.

**Ensuring availability** Another problem arises when the responsibility to store key material is delegated solely to external custodians who have no ex-

licit incentive to make sure the key stays available: custodians may be lazy and stop storing the key material as a way to save space and money, relying on the assumption that the other custodians will act honestly and store their corresponding shares. Even in the case in which all custodians have honest intentions, a client with a large sum of money in their threshold wallet may still wish to intermittently check that a custodian has access to its key material. To our knowledge, no wallet explicitly implements such a feature, although a similar effect can be achieved by requesting approval of an empty transaction, since this makes it clear that at least  $t$  of the parties still hold their shares (although not necessarily which ones). A more targeted audit could be implemented via generic zero-knowledge proofs requiring a party to prove knowledge of the  $i$ th key share using some time-based challenge, but the practical efficiency of such a proof is unclear.

## 5.1 Our Results

We introduce a new type of wallet which combines offline components with the threshold wallet approach to achieve stronger security guarantees. In our model, each threshold signer consists of two parties: an online *hot* storage and an offline, resource-constrained *cold* storage, e.g., a secure enclave, trusted execution environment, or perhaps something even more sophisticated. Producing a threshold signature on any message should require the involvement of both the hot and cold parties while minimizing the computation and communication on the part of the cold party. Wallet owners should also be able to request proofs from any party, hot or cold, that it retains its share of the secret key. Finally, it should be possible to periodically refresh the shares of the online parties to thwart an adversary who slowly and incrementally corrupts parties in the system. We describe each of our contributions in more detail below.

**Stronger threat model** In a hot-cold threshold wallet, an attacker must corrupt *both* the cold and hot components of a signer to obtain its key share. This requirement to corrupt a threshold  $t$  of hot-cold *pairs* is different from a generic  $2t$ -out-of- $2n$  threshold wallet, since the attacker cannot forge a signature by corrupting any arbitrary set of  $2t$  parties: in our model, corrupting, e.g.,  $2t$  hot parties should be of no use in forging a signature (in fact, even corrupting all  $n$  hot parties should be useless). Indeed, our threat model is instead comparable to a Boolean signing policy which requires at least  $t$  pairs of hot *and* cold parties to contribute, which is much more difficult to attack since the cold components are almost always offline.

**Threshold BLS construction** We show how to construct such a hot-cold threshold signing protocol for the BLS signature scheme [BLS01, Bol03]. Although ECDSA [GGN16, DKLs18, LN18, GG18, AHS20, GKSŠ20, DJN+20, CGG+20, CCL+20, CCL+21, Pet21, ANO+22] and Schnorr [KG20, BCK+22, BLM22] are the most popular threshold signature schemes in the literature, their

more complicated structure makes a threshold signing procedure with offline parties difficult. BLS signatures have the advantage of being simple to understand and deploy. This has led to their widespread use in production systems, including in Ethereum’s consensus protocol [Edg23, §2.9.1], Filecoin [Fil], transactions on the Chia Network [Chi24], and a BLS smart contract wallet [Pri22]. With the event of account abstraction on Ethereum [Eth24], users will be able to specify alternative signature schemes to verify their transactions, further easing the adoption of BLS-based wallets. The homomorphic structure of BLS allows us to give a simple non-interactive hot-cold threshold signature protocol. Our construction also has the added benefit that the cold parties can generate their secret key shares independently, without interacting with the hot parties or with each other.

**Proofs of remembrance** We show how the cold and hot parties in our protocol can produce “proofs of remembrance”, i.e., zero-knowledge proofs that they still possess their key material. In order to support proactive refreshes (see below), our proof systems must accommodate periodic updates to individual key shares while guaranteeing that the underlying secret key is still available. We show how to meet both needs simultaneously, allowing a client to intermittently and independently audit its (hot or cold) custodians. This allows it to ensure that its key material has not been overwritten or forgotten, and its funds are still accessible.

**Proactive refresh** Many threshold wallets support proactive refresh [KMOS21], meaning secret key shares are regularly updated. This forces an attacker to compromise at least  $t$  parties within a single epoch in order to mount a successful attack: otherwise, any partial key material which has been obtained is made obsolete by the refresh operation. Our protocol allows proactive refresh of the hot key shares while still letting hot parties prove knowledge of those shares and their consistency with the (unchanging) verification key.

**Efficient open-source implementation** We implemented our protocol and show that it is practically efficient for essentially all reasonable settings of  $t, n$ . Producing a signature takes less than 1ms and computing proofs of remembrance is on the order of milliseconds. Our implementation is publicly available in Hyperledger Labs<sup>15</sup> and is Apache 2.0 licensed.

## 5.2 Technical overview

We will use the superscripts *hot* and *cold*, respectively, to denote the hot and cold components of some value, and a subscript  $i$  to denote the value corresponds to the  $i$ th party. For example, the  $i$ th party’s cold signature is written as  $\sigma_i^{\text{cold}}$ . We use the words “user” and “client” interchangeably to refer to the wallet owner.

<sup>15</sup><https://github.com/hyperledger-labs/agora-key-share-proofs>

A starting point for constructing a threshold signature with our desired access structure would be to first compute a  $t$ -out-of- $n$  sharing  $\text{sk}_1, \dots, \text{sk}_n$  of the signing key  $\text{sk}$ , then give each hot-cold pair a 2-out-of-2 (additive) sharing  $\text{sk}_i^{\text{hot}}, \text{sk}_i^{\text{cold}}$  of one of the threshold shares. The signing protocol has to be designed carefully, since we need to ensure that any communication from the cold party to the hot is “bound” to the message  $m$  being signed. Otherwise, the hot storage could replay the communication and produce a signature on some other message  $m' \neq m$  without the cold storage’s cooperation, violating our threat model.

Our scheme takes advantage of the natural homomorphism of BLS signatures to use the additive sharing idea. At a high level, the cold and hot parties will receive shares  $r$  and  $\text{sk}_i + r$ , respectively, of the threshold signing key share. Then the cold storage can send the hot storage a partial signature  $\sigma_i^{\text{cold}} := H(m)^r$  which is “bound” to the message  $m$ , and the hot storage computes its own partial signature  $\sigma_i^{\text{hot}} := H(m)^{\text{sk}_i + r}$ . The threshold BLS signature  $\sigma_i$  can be computed by the hot storage as  $\sigma_i^{\text{hot}} / \sigma_i^{\text{cold}} = H(m)^{\text{sk}_i}$ . This scheme also enables proactive refresh of the hot shares basically “for free” due to the malleability of the additive sharing: the wallet owner can simply send every hot storage a  $t$ -out-of- $n$  sharing of zero, which the hot storage adds to its current share.

Our idea for realizing this additive sharing is to allow each cold party to sample an encryption key-pair  $(\text{ek}_i, \text{dk}_i)$  and let the cold share  $r$  be a deterministic function of  $\text{ek}_i$  and the client signing key  $\text{sk}$ . In particular, we want to set  $r := \mathcal{H}(\text{ek}_i^{\text{sk}})$  for a carefully-designed efficient hash function  $\mathcal{H}$ . Put another way, this means the hot key share will be an encryption of  $\text{sk}_i$  under the cold party’s public key  $\text{ek}_i$ . This allows the hot key material to be computed by a key generation protocol which outputs the verification key  $\text{vk} = g^{\text{sk}}$  and each hot party’s key share  $\text{sk}_i + \mathcal{H}(\text{ek}_i^{\text{sk}})$  without interacting with the cold parties. The crucial piece is that each cold encryption key-pair will be instantiated in the same group and using the same generator as the signing key-pair, so  $\text{ek}_i^{\text{sk}} = (g^{\text{dk}_i})^{\text{sk}} = \text{vk}^{\text{dk}_i}$ . Thus, given the verification key, each cold storage can now independently recover its signing key share  $r$  as  $\mathcal{H}(\text{vk}^{\text{dk}_i})$ . This means that a partial signature is effectively computed by decrypting the hot key share “in the exponent” of the partial BLS signature.

To prove remembrance, each type of party uses its own proof system. For cold parties, a standard proof of knowledge of discrete logarithm (for  $\text{dk}_i$  corresponding to  $\text{ek}_i$ ) suffices. For the hot parties, the relation is more complicated since the shares are no longer simply points on a degree- $t$  polynomial. We give a proof system based on KZG commitments which leverages their multiplicative homomorphism to enable compatibility with hot share refreshes.

### 5.3 Related Work

Blokh et al. [BMP22] describe another threshold signing protocol which combines online (hot) and offline (cold) parties. Their protocol is tailored to ECDSA signatures and uses  $n$  hot parties and single cold party. These  $(n + 1)$  parties are independent (i.e., the cold party is not paired with any hot party, as in

our setting); thus, their security guarantee is still a classic  $t$ -out-of- $n$  threshold guarantee, unlike our protocol, which is secure up to corruption of  $t$  *pairs*. Furthermore, in their protocol, hot parties engage in an MPC to generate a pre-signature, which is then finalized and output by the cold party. This is in contrast to our protocol, where the cold parties send messages to their corresponding hot parties, and the hot parties output the final signature (shares).

## 5.4 Model

Let  $I_1, \dots, I_n$  be parties (each representing an institution) who will store shares of some user's signing key  $\text{sk}$ . Each institution  $I_i$  controls two parties: a hot storage ( $P_i^{\text{hot}}$ ) and a cold storage ( $P_i^{\text{cold}}$ ). Thus we represent an institution by the tuple  $I_i = (P_i^{\text{hot}}, P_i^{\text{cold}})$ . As in the standard threshold wallet setting, the hot parties are connected to each other via authenticated (but not private) channels and we also assume the parties can send broadcast messages (e.g. by posting to a blockchain). In contrast, each cold storage is connected by an authenticated channel only to its corresponding hot storage. The channel is only active during the signing phase, further reducing the cold party's attack surface. (For example, the cold storage could be a read-only USB device which is plugged into a PC (the hot storage) only briefly to produce a signature.) An illustration of this model is given in Figure 11 for  $n = 3$ .

We assume  $P_i^{\text{hot}}$  has more storage space and computational power, while  $P_i^{\text{cold}}$  has limited storage (in particular, we want the space complexity to be independent of the number of users in the system). Therefore, our protocol aims to minimize the computation done by the cold storage.

## 5.5 Malleable Encryption for eXponents (MEX)

As explained above, the core idea of our construction is for each hot party to store an encryption of the institution's signing key share  $\text{sk}_i$ , with the corresponding decryption key kept on the cold storage. That is, each institution will generate an encryption key pair  $(\text{ek}_i, \text{dk}_i)$  and store the hot key share  $\text{sk}_i^{\text{hot}} := \text{Enc}(\text{ek}_i, \text{sk}_i)$  in the hot storage and  $\text{sk}_i^{\text{cold}} := \text{dk}_i$  in the cold storage. We want to enable threshold signing of a message  $m$  by allowing the hot and cold parties to derive signature shares  $\sigma_i^{\text{hot}}, \sigma_i^{\text{cold}}$  for  $m$  from their secret material  $\text{sk}_i^{\text{hot}}, \text{sk}_i^{\text{cold}}$  (the secret key and ciphertext, respectively). Together, the signature shares can be used to recover a partial signature  $\sigma_i$  of  $m$  under  $\text{sk}_i$ .

In this section, we describe an encryption scheme based on ElGamal [EIG84] whose malleability allows decryption of the hot key share “in the exponent” of a partial BLS signature. Recall that the ElGamal ciphertext for a message  $m \in \mathbb{G}$  is computed as  $(g^r, \text{ek}^r \cdot m) \in \mathbb{G}^2$  where  $\mathbb{G}$  is a prime order group. In our case, however,  $m = \text{sk}_i$  will be a scalar element of  $\mathbb{Z}_p$  (an “exponent”). Adapting the encryption scheme to scalar messages, we can compute the ciphertext as  $(g_2^r, \mathcal{H}(\text{ek}^r) + m)$ , where  $\mathcal{H}$  is some function which maps  $\text{ek}^{\text{sk}}$  to  $\mathbb{Z}_p$  in a way that masks  $m$ . We will see below that this can be achieved by defining our encryption key  $\text{ek}$  to be a tuple  $(\text{ek}_1, \text{ek}_2) \in \mathbb{G}^2$  and letting  $\mathcal{H} : \mathbb{G}^2 \rightarrow \mathbb{Z}_p$ . Now

we can mask  $m$  with the output of  $\mathcal{H}$ , and a cold party can undo this masking (in the exponent of the BLS signature) using  $g^r$  and  $\text{dk}_1, \text{dk}_2$ . We call the resulting scheme Malleable Encryption for eXponents (MEX).

Like the original ElGamal encryption and as the name suggests, MEX is malleable (in this case, additively rather than multiplicatively), which allows “shifting” of the message  $m$  in a ciphertext by an additive factor (via the Shift algorithm). We will use this property to enable proactive refresh of the hot (encrypted) key shares.

**Construction 10 (MEX).** *Let  $\mathbb{G}$  be a DLog-hard group of order  $p$  with generator  $g$ . Let  $\mathcal{H} : \mathbb{G} \rightarrow \mathbb{Z}_p$  be a hash function.*

- $(\text{ek}, \text{dk}) \leftarrow \text{KGen}(1^\lambda)$ : *Sample  $\text{dk} \xleftarrow{\$} \mathbb{Z}_p$ . Set  $\text{ek} := g^{\text{dk}}$  and output  $(\text{ek}, \text{dk})$ .*
- $ct \leftarrow \text{Enc}(\text{ek}, m; r)$ : *Given an encryption key  $\text{ek} \in \mathbb{G}$  and a message  $m \in \mathbb{Z}_p$ , use randomness  $r \in \mathbb{Z}_p$  to compute the ciphertext  $ct := (g^r, m + \mathcal{H}(\text{ek}^r))$ .*
- $m' \leftarrow \text{Dec}(\text{dk}, ct)$ : *Given a secret key  $\text{dk} \in \mathbb{Z}_p$  and a ciphertext  $ct \in \mathbb{G} \times \mathbb{Z}_p$ , parse  $ct$  as  $(ct_0, ct_1)$  and return  $ct_1 - \mathcal{H}(ct_0^{\text{dk}})$ .*
- $ct' \leftarrow \text{Shift}(ct, \delta)$ : *Given a ciphertext  $ct \in \mathbb{G} \times \mathbb{Z}_p$  and a shift  $\delta \in \mathbb{Z}_p$ , parse  $ct$  as  $(ct_0, ct_1)$  and output the shifted ciphertext  $ct' := (ct_0, ct_1 + \delta)$ .*

### 5.5.1 Additive Secret Sharing from MEX

The Enc algorithm in Construction 10 takes an explicit randomness input  $r$ . In the context of our wallet construction, encryption will take place at the same time as signing key generation, and instead of sampling fresh randomness  $r \in \mathbb{Z}_p$  for each hot party’s ciphertext (hot key share), we will sample a single value  $r$ . The signing key-pair is set to  $(\text{vk}, \text{sk}) := (g^r, r)$ .<sup>16</sup> The result is that each party  $P_i^{\text{hot}}$ ’s ciphertext uses the mask  $\mathcal{H}(\text{ek}_i^{\text{sk}}) = \mathcal{H}(\text{vk}^{\text{dk}_i})$ , which allows the corresponding cold party  $P_i^{\text{cold}}$  to decrypt using only a client’s verification key  $\text{vk}$  and without receiving or storing any additional per-client randomness.

Because the input to  $\mathcal{H}$  is no longer uniformly random, we now need  $\mathcal{H}$  to be a hash function where the Leftover Hash Lemma (see Section 2.10) holds on random inputs. In order for the output of  $\mathcal{H}$  to have sufficient entropy to mask  $m$ , this requires two group elements as input. Therefore, in our wallet construction we will use  $\text{ek} := (g^{\text{dk}_1}, g^{\text{dk}_2})$  and  $ct := m + \mathcal{H}(\text{ek}_1^{\text{sk}}, \text{ek}_2^{\text{sk}})$ .

Although any function  $\mathcal{H}$  which meets the above requirements suffices, it is desirable to find a very efficient construction since  $\mathcal{H}$  will have to be computed by the cold party at signing time. One such  $\mathcal{H}$  is a random subset sum. In more detail,  $\mathcal{H}$  first represents its inputs  $x_1, x_2 \in \mathbb{G}$  as  $\ell$ -bit vectors  $\mathbf{x}_1, \mathbf{x}_2 \in \{0, 1\}^\ell$ , where  $\ell = \log p$ . Let  $\mathbf{r}_1, \mathbf{r}_2 \in \mathbb{Z}_p^{2\ell}$  be (public) uniform vectors with  $\mathbf{r}_k = (\mathbf{r}_{k,0}, \mathbf{r}_{k,1})$  for  $k = 1, 2$ . We will use bracket notation to index into the vector,

<sup>16</sup>This means we can leave out the redundant first element, so each ciphertext will consist of a single group element.

i.e.,  $\mathbf{r}_{1,0}[i]$  is the  $i$ th element of  $\mathbf{r}_{1,0}$ . Let  $\mathcal{H}(x_1, x_2) := \mathcal{H}'(\mathbf{r}_1, \mathbf{x}_1) + \mathcal{H}'(\mathbf{r}_2, \mathbf{x}_2)$ , where  $\mathcal{H}' : \mathbb{Z}_p^{2\ell} \times \{0, 1\}^\ell \rightarrow \mathbb{Z}_p$  is the subset sum function

$$\mathcal{H}'(\mathbf{r} := (\mathbf{r}_0, \mathbf{r}_1), \mathbf{x}) := \sum_{b_i \in \mathbf{x}} \mathbf{r}_{b_i}[i]$$

When we want to be specific about the randomness used in  $\mathcal{H}$ , we write  $\mathcal{H}(x_1, x_2; \mathbf{k})$  for  $\mathbf{k} \in \mathbb{Z}_p^{4\ell}$ . By Lemma 1 in Section 2.10, the output of  $\mathcal{H}$  is statistically indistinguishable from uniform.

## 5.6 Proofs of Remembrance

We will use non-replayable zero-knowledge proofs of knowledge (ZKPoKs) for two languages. We refer the reader to [Tha23] for the definition of a ZKPoK. The PoKs for both our hot and cold parties are Sigma protocols, made non-interactive via the Fiat-Shamir transform [FS87]. Non-replayability is enforced by including some unpredictable timestamp (e.g., current block number of some blockchain) in the payload of the Fiat-Shamir hash.

To prove knowledge of the cold share, i.e., its decryption key, each cold storages will use a proof of knowledge of discrete logarithm  $\Pi_{\text{DL}}$  for the language  $\{y \in \mathbb{G} : \exists w \in \mathbb{Z}_p \text{ s.t. } y = g^w\}$ . This can be instantiated with the classic Schnorr protocol [Sch90].

The proof of knowledge for the hot storages is more complicated. At setup time, each hot storage must receive, along with its encrypted share, a proof of knowledge for the share's well-formedness. This should prove that the hot share equals  $\mathcal{H}(\text{ek}_{i,1}^x, \text{ek}_{i,2}^x) + x_i$  for some secret value  $x$  such that  $g^x = vk$  and  $x_i = \text{Share}(x, t, n)$ , and that the same value of  $x$  is used for every party. Our core idea is to use a KZG commitment to the polynomial used in the Shamir sharing of  $x$  and distribute an evaluation proof to each hot storage. The additive homomorphism of the commitments allows the public commitment, as well as each party's evaluation proof, to be updated when the shares are refreshed. We begin with a strawman example where the hot storage shares are unencrypted and then show how to adapt the construction to encrypted shares.

### 5.6.1 PoK of (Unencrypted) Key Share

Let  $\text{crs}$  be a degree- $(t-1)$  KZG CRS. At time  $T = 0$ , the client  $C$  picks a random degree- $(t-1)$  polynomial  $f_0(X) \in \mathbb{Z}_p[X]$  (its evaluation at 0 will be the signing key  $\text{sk}$ ) and publishes  $\text{com}_0 \leftarrow \text{KZG.Com}(\text{crs}, f_0(X))$ . Each hot storage  $P_i^{\text{hot}}$  receives an opening  $f_0(i)$  (i.e., the key share  $\text{sk}_i$ ) and evaluation proof  $\pi_{0,i}$ .

Whenever it wants the servers to refresh their shares and thus transition from epoch  $T-1$  to  $T$ ,  $C$  will commit to (as  $\text{ucom}_T$ ) a new random degree- $t$  polynomial  $z_T(X)$  such that  $z_T(0) = 0$ , publish an evaluation proof  $\zeta_{T,0}$  at  $X = 0$ , and send each  $P_i^{\text{hot}}$  its opening  $z_T(i)$  and the corresponding evaluation proof  $\zeta_{T,i}$ . Everyone can check the correctness of the update by verifying  $\zeta_{T,0}$  with respect to  $\text{ucom}_T$ . If the check passes, they can compute the commitment to

the new polynomial  $f_T(X)$  homomorphically from the commitments to  $f_{T-1}(X)$  and  $z_T(X)$ , namely as  $\text{com}_T = \text{com}_{T-1} \cdot \text{ucom}_T$ . Then each party verifies its own update proof  $\zeta_{T,i}$  before updating its previous key share  $f_{T-1}(i)$  and proof  $\pi_{T-1,i}$ , respectively, to  $f_T(i) := f_{T-1}(i) + z_T(i)$  and  $\pi_{T,i} := \pi_{T-1,i} \cdot \zeta_{T,i}$ . By the homomorphic nature of the KZG commitment scheme,  $P_i^{\text{hot}}$  now has an evaluation of  $(f_{T-1} + z_T)(X) = f_T(X)$  at  $i$  and a corresponding evaluation proof  $\pi_{T,i}$ .

There is a problem with this scheme:  $P_i^{\text{hot}}$  needs to reveal  $f_T(i)$  in order for anyone to verify  $\pi_{T,i}$ ...but  $f_T(i)$  is its current key share! The solution is for  $P_i^{\text{hot}}$  to prove it knows  $f_T(i)$  in *zero-knowledge* via a blinded KZG evaluation proof (a modified version of the protocol in [ZBK<sup>+</sup>22, §6.1]). It commits to the key share  $f_T(i)$  using a Pedersen commitment  $\text{com}_{\text{ped}} := g_1^{f_T(i)} h_1^r$  and computes  $\pi_{\text{ped}} \leftarrow \Pi_{\text{ped}}.\text{Prove}(\text{com}_{\text{ped}}; (f_T(i), r))$ . It also samples  $s \xleftarrow{\$} \mathbb{Z}_p$  and computes a blinded version of the evaluation proof as  $\bar{\pi}_{T,i} := \pi_{T,i} h_1^s$ . The final ZKPoK is defined as  $(\text{com}_{\text{ped}}, \pi_{\text{ped}}, \bar{\pi}_{T,i}, g^{s_{T,i}(\tau)})$ , where  $s_{T,i}(X) := -r - s(X - i)$ . The client accepts if and only if

$$e(\text{com}_T / \text{com}_{\text{ped}}, g_2) \stackrel{?}{=} e(\bar{\pi}_{T,i}, g_2^r / g_2^i) \cdot e(h_1, g_2^{s_{T,i}(\tau)})$$

(where the boxed parts are changes to the original KZG verification check due to the blinding).

### 5.6.2 PoK of Encrypted Key Share

Next, we modify the previous construction to accommodate an *encrypted* initial key share  $\tilde{x}_i := \mathcal{H}(\text{ek}_{i,1}^x, \text{ek}_{i,2}^x) + x_i$ , where  $x = f_0(0)$  and  $x_i = f_0(i)$ . After having computed every party's plaintext share  $x_i$  (as above), the client  $C$  will compute each encrypted key share  $\tilde{x}_i$  and interpolate the degree- $(n-1)$  polynomial  $\tilde{f}_0(X)$  where  $\tilde{f}_0(i) = \tilde{x}_i$  for  $i \in [n]$ . For now, we assume the  $\tilde{x}_i$  and  $f_0(X)$  are computed correctly (we will return to this assumption in Section 5.7). Thus, we don't prove the correctness of the  $\tilde{x}_i$  values themselves, only that they are equal to  $\tilde{f}_0(i)$  where  $\tilde{f}_0(X)$  is fixed for all parties.

$C$  commits to  $\tilde{f}_0(X)$  publicly and, in a similar fashion as before, sends each hot storage  $P_i^{\text{hot}}$  the opening  $\tilde{f}_0(i) =: \tilde{x}_i$  and the corresponding evaluation proof  $\pi_{0,i}$ . Now the hot storage can prove remembrance of its current share  $\tilde{f}_T(i)$  in zero-knowledge in the same way as before, namely by committing to the share and blinding the evaluation proof  $\pi_{T,i}$  as described in the previous section.

Share refreshes in epoch  $T$  also proceed as before with a commitment  $\text{ucom}_T$  to a polynomial  $z_T(X)$  such that  $z_T(0) = 0$  (confirmed via a public evaluation proof  $\zeta_{T,0}$  at  $X = 0$ ). Parties receive their update value  $z_T(i)$  and corresponding evaluation proof  $\zeta_{T,i}$ , and can update their (now encrypted) share homomorphically just like before. (This still works because our encryption scheme allows additive shifts of the plaintext via addition to the ciphertext.) The only difference is that, because the encrypted shares now lie on a degree- $(n-1)$  polynomial instead of a degree- $(t-1)$  polynomial, the KZG CRS must accommodate polynomials up to degree  $n-1$ . (In practice, because different clients in the system

may chose different values of  $n$ , the KZG CRS will actually have some degree  $d$  which is as large as the maximum allowed value of  $n - 1$ .) As with the original polynomial  $\tilde{f}_0(X)$ , we assume  $z_T(X)$  is chosen honestly by  $C$ . In Section 5.7.3, we show how to avoid trusting  $C$  in the refresh stage.

The final hot proof of remembrance is summarized as  $\Pi_{\text{EKS}}$  in Figure 12.

## 5.7 Hot-Cold Threshold BLS

In this section, we show how to use the MEX from Section 5.5 and the proofs of remembrance from Section 5.6 to construct a hot-cold threshold wallet for BLS signatures (recalled in Section 2.7.1) with proofs of remembrance and proactive refresh of the hot shares.

Let  $\mathbb{G}_1, \mathbb{G}_2$  be elliptic curve groups of order  $p$  generated by  $g_1$  and  $g_2$ , respectively, and  $e : \mathbb{G}_1 \times \mathbb{G}_2 \rightarrow \mathbb{G}_T$  is an efficiently computable asymmetric (type-3) pairing between them. Since  $\text{vk} \in \mathbb{G}_2$ , we will also instantiate the MEX over  $\mathbb{G}_2$ . Let  $H : \{0, 1\}^* \rightarrow \mathbb{G}_1$  and  $\mathcal{H} : \mathbb{G}_2^2 \rightarrow \mathbb{Z}_p$  be hash functions as defined in Section 2.7.1 and Section 5.5, respectively.

**Subprotocols** We assume the existence of the following ideal functionalities, which we will use as building blocks for our protocol:

**(Encrypted) secret share generation  $\mathcal{F}_{\text{SS}}$ :** Presented in Figure 13, this functionality is executed between a client  $C$  and a set of institutional entities. The functionality allows the client to choose which institutional entities it wants to use. We require that the client provide the public keys of the institutional servers that it wants to engage. A direct way to implement the  $\mathcal{F}_{\text{SS}}$  functionality would be for (trusted)  $C$  to execute the steps of  $\mathcal{F}_{\text{SS}}$  on input  $\text{SSSetup}$  locally and send  $\tilde{x}_i$  to  $P_i^{\text{hot}}$  for each  $i$  via a point-to-point channel. While this suffices for a number of applications, we model it as an abstract ideal functionality as we will be interested in settings where security is desired even if  $C$  (i) does not have access to a source of true randomness, or (ii) is (or, may in future be) corrupted. In Section 5.7.3, we show that one can use an additional proof system  $\Pi_{\text{Ref}}$  and a public bulletin-board with limited programmability to avoid trusting  $C$  beyond the key generation phase. We leave a fully decentralized key generation protocol to future work.

**Public key infrastructure  $\mathcal{F}_{\text{PK}}$ :** Finally, we assume a functionality  $\mathcal{F}_{\text{PK}}$  (Figure 14) which allows a party (institutional cold servers in our case) to obtain a secret (decryption) key  $\text{dk}$  sampled from  $\mathbb{Z}_p$  while its public (encryption) key  $\text{ek} := g_2^{\text{dk}}$  is made public, and can be retrieved reliably by any client. Again this functionality can be implemented by a party executing it locally. We abstract it out to separate the implementation details of this functionality from our modeling.

**Construction** Our protocol for BLS signatures is given in Figures 15 and 16. Each cold storage is set up separately and independently of any client using the **ColdRegister** protocol. When a client registers, it specifies a set of  $n$  institutions  $\mathcal{I}$  and a threshold  $t \leq n$  of them required for signing. The **ClientRegister** protocol is an interactive protocol between  $C$  and the  $n$  hot parties specified by  $\mathcal{I}$  which outputs a verification key  $\text{vk}$  to the client and an encrypted secret key share  $\tilde{x}_i$  to each hot party. Each hot party also receives a proof  $\pi_i$  which will allow it to prove that  $\tilde{x}_i$  was the output of **ClientRegister**.

To sign a message  $m$  on behalf of  $C$ , each institution (consisting of a hot and cold party) separately produces a partial signature on  $m$ . Upon receiving a signature request (which in most implementations would be passed to the cold party via the hot party), each component can honor the request by producing a partial signature  $\sigma_i^{\text{hot}}$  or  $\sigma_i^{\text{cold}}$ , respectively, which are combined by the hot party into  $\sigma_i$ .

Proving remembrance of each party's key material is done via **CProof** and **HProof**, respectively. We write that  $P_i^{\text{cold}}$  sends its proof directly to  $C$ , which in practice can be achieved by passing the message via  $P_i^{\text{hot}}$  assuming eventual delivery. Finally, the hot key shares can be proactively refreshed via an interactive protocol **ShareRefresh** between  $C$  and the hot parties, which is similar to **ClientRegister** and outputs some update information  $\delta_i$  and a proof  $\zeta_i$  of its correctness to each hot party.

**Correctness** Let  $\mathcal{I}$  be the set of  $n$  institutions  $C$  registers with using threshold  $t$ . For  $i \in [n]$ , let  $\text{ek}_i$  be the output of **ColdRegister** for  $P_i^{\text{cold}}$ ,  $\text{vk}$  be the output of **ClientRegister**,  $\text{com}_T$  be the polynomial commitment after  $T$  executions of **ShareRefresh**, and  $\pi_i^{\text{hot}}$  (resp.  $\pi_i^{\text{cold}}$ ) be the output of **HProof** for  $P_i^{\text{hot}}$  and  $C$  (resp. **CProof**,  $P_i^{\text{cold}}$ , and  $C$ ). For correctness, we require that for all  $T$ , if there exists some set  $S = \{i : i \in [n]\}$  with  $|S| \geq t$  such that  $\Pi_{\text{EKS}}.\text{Vrfy}(\text{crs}, \text{com}_T, \pi_i^{\text{hot}}) = 1$  and  $\Pi_{\text{DL}}.\text{Vrfy}((\text{ek}_i, g_2), \pi_i^{\text{cold}}) = 1$  for all  $i \in S$ , then  $\text{BLS}.\text{Vrfy}(\text{vk}, m, \text{BLS}.\text{Reconstruct}(\{\sigma_i\}_{i \in S})) = 1$  with all but negligible probability, where  $\sigma_i$  is the output of **TSign** for  $P_i^{\text{hot}}$ ,  $C$ ,  $m$ .

Recall that **TSign** outputs computes  $\sigma_i$  as  $\sigma_i^{\text{hot}}/\sigma_i^{\text{cold}}$ , which by construction equals  $H(m)^{\text{sk}_i + \mathcal{H}(\text{ek}_i^{\text{sk}})} \cdot H(m)^{-\mathcal{H}(\text{vk}^{\text{dk}_i})} = H(m)^{\text{sk}_i} = \text{BLS}.\text{TSign}(\text{sk}_i, m)$ . Thus correctness follows by construction, the soundness of  $\Pi_{\text{DL}}$ ,  $\Pi_{\text{EKS}}$ , and the correctness of threshold BLS.

**Efficiency and compactness of cold storage** We wish to point out that our construction optimizes storage-, computation-, and communication-efficiency for the cold storage. Each  $P_i^{\text{cold}}$  only stores a single decryption key  $\text{dk}_i \in \mathbb{G}_2^2$ , regardless of the number of clients registered with its institution. To produce a cold partial signature, it computes two  $\mathbb{G}_2$  exponentiations, one addition in  $\mathbb{Z}_p$ , and a single evaluation of  $\mathcal{H}$ , which is highly efficient since it is a simple subset sum (see Section 5.5). Computing a proof of remembrance requires 2  $\mathbb{G}_2$  exponentiations, 1 hash function evaluation (for Fiat-Shamir), and 2 additions and multiplications each in  $\mathbb{Z}_p$ . Finally, in terms of communication, the cold

storage only needs to send a single  $\mathbb{G}_1$  element per signing operation. A cold proof of remembrance consists of 2  $\mathbb{G}_2$  and 2  $\mathbb{Z}_p$  elements.

### 5.7.1 Security Analysis

We prove our scheme secure in the universal composability framework<sup>17</sup>, which we summarize in Section 2.11.

Messages to and from the ideal functionalities consist of two pieces: a *header* and the *contents*. The header normally consists of a session identifier `sid`, a description of the action the functionality should take/has taken, and the sender/recipient. In this paper, we will use the convention of putting the message contents in parentheses so it is clear where the (public) header ends and the (private) contents begin, e.g.,  $(\text{sid}, \text{Action}, P_{\text{sender}}, (\text{contents}))$  or  $(\text{sid}, \text{ActionDone}, P_{\text{recipient}}, \text{publicvars}, (\text{contents}))$ .

**Ideal Functionality** We now present our hot-cold threshold BLS functionality  $\mathcal{F}_{\text{HC}}$ , whose interfaces can only be called by *either* an institutional hot or cold storage (specified by the superscripts *hot* and *cold*) or a client. For readability, we split  $\mathcal{F}_{\text{HC}}$  into three figures. The first, Figure 17, describes how parties register in the system. The signing, share refresh, and proof of remembrance interfaces of  $\mathcal{F}_{\text{HC}}$  are described in Figure 18.

The most complicated part of the functionality is the signing interface, which provides partial BLS signatures  $\sigma_i$  on requested messages. For uncorrupted institutions  $I_i$  (that is, neither  $P_i^{\text{cold}}$  and  $P_i^{\text{hot}}$  are corrupt),  $\sigma_i$  is computed honestly. If the hot party has been corrupted but the cold remains honest, the functionality asks the adversary whether to use the correct value for the hot signature; if so, it computes  $\sigma_i$  correctly and also sends the cold signature to the adversary. Otherwise, it outputs  $\sigma_i = \perp$  and sends  $H(m)^r$  for a uniform  $r$  to  $\mathcal{A}$  (as the “corresponding” cold signature). (The idea is that in this case, the hot signature is incorrect so  $\sigma_i$  will not verify, and the cold signature should be “useless” without it: it should look random to the adversary.) If the hot party is honest and the cold is corrupt, the functionality behaves in the same way but with the hot and cold roles reversed. Finally, if both parties in a pair are corrupt, the adversary will get no information about the hot or cold partial signatures from the functionality, which only outputs either the correct  $\sigma_i$  or  $\perp$ , depending on whether the adversary says to compute the hot and cold partial signatures correctly.

We will argue that this implements threshold BLS signatures, so the security of a protocol implementing  $\mathcal{F}_{\text{HC}}$  follows from security of threshold BLS.

**Adversarial interference** Figure 19 gives the leak and tamper interfaces of  $\mathcal{F}_{\text{HC}}$ , which an adversary can use to interfere with the information stored by the hot and cold storages in the system. We also give an explicit corruption

<sup>17</sup>Specifically, we use the version presented in [CLOS02].

<sup>18</sup>We assume share refreshes are sequential and delivery to all  $P_i$  precedes any new refreshes.

interface, which only allows non-adaptive corruptions of the cold and hot parties (in the latter case, on a per-epoch basis). The interfaces also capture the fact that the client  $C$  is out of scope for corruption.

**Theorem 6** (security). *Our hot-cold threshold wallet construction (??) UC-realizes  $\mathcal{F}_{\text{HC}}$  in the  $\mathcal{F}_{\text{SS}}, \mathcal{F}_{\text{PK}}$ -hybrid model.*

*Proof.* Let  $\mathcal{A}$  be the adversary interacting with the parties (namely,  $P_1^{\text{hot}}, P_1^{\text{cold}}, \dots, P_n^{\text{hot}}, P_n^{\text{cold}}, C$ ) running the protocol presented in ??. We will construct a simulator  $\mathcal{S}$  running in the ideal world against  $\mathcal{F}_{\text{HC}}$  so that no environment  $\mathcal{E}$  can distinguish an execution of the ideal-world interaction from the real protocol.  $\mathcal{S}$  will interact with  $\mathcal{F}_{\text{HC}}$ ,  $\mathcal{E}$ , and invoke a copy of  $\mathcal{A}$  to run a simulated interaction of the protocol (we call this simulated interaction between  $\mathcal{A}$ ,  $\mathcal{E}$ , and the parties the *internal interaction* to distinguish it from the *external interaction* between  $\mathcal{S}$ ,  $\mathcal{E}$ , and  $\mathcal{F}_{\text{HC}}$ ).

Each protocol/algorithm begins with a party receiving some input. In the ideal world, this input is received by some dummy party, who immediately copies it to its outgoing communication tape where  $\mathcal{S}$  can read it (public header only) and potentially deliver it to the ideal functionality  $\mathcal{F}_{\text{HC}}$ . (Recall that for simplicity we assume authenticated communication, so  $\mathcal{S}$  cannot modify the messages it delivers to/from  $\mathcal{F}_{\text{HC}}$ .) To complete the protocol,  $\mathcal{S}$  will deliver the response of  $\mathcal{F}_{\text{HC}}$  to the dummy party, who copies it to its output tape (which is visible to  $\mathcal{E}$ ).

**Message delivery**  $\mathcal{S}$  waits to deliver any messages until  $\mathcal{A}$  delivers the corresponding message in the internal interaction.

**Corruptions** Whenever  $\mathcal{A}$  corrupts a party  $P_i^{\text{cold}}$  or  $P_i^{\text{hot}}$  in the internal execution,  $\mathcal{S}$  corrupts the corresponding dummy party (via the **Corrupt** interface).

**Leak and Tamper** Whenever  $\mathcal{A}$  leaks or tampers with the inputs of a party in the internal execution,  $\mathcal{S}$  uses the corresponding interface of  $\mathcal{F}_{\text{HC}}$  to learn/change the same information (it can use any functions  $f, g$  for tampering).

**Cold Registration**  $\mathcal{S}$  will deliver the message  $(\text{sid}, \text{ColdRegister}, P_i^{\text{cold}})$  from  $\tilde{P}_i^{\text{cold}}$  to  $\mathcal{F}_{\text{HC}}$  once  $\mathcal{A}$  delivers  $(\text{sid}, \text{PKSetup}, P_i^{\text{cold}})$  to  $\mathcal{F}_{\text{PK}}$  in the internal interaction.

- If  $\tilde{P}_i^{\text{cold}}$  is corrupt,  $\mathcal{S}$  records  $(P_i^{\text{cold}}, \text{ek}_i^*, \text{corrupt} = 1)$  in a local database  $L'_{\text{cold}}$ , where  $\text{ek}_i^*$  is the value sent by  $\mathcal{A}$  on (the corrupted)  $\tilde{P}_i^{\text{cold}}$ 's behalf.
- Otherwise, if  $\tilde{P}_i^{\text{cold}}$  is honest, it stores  $(P_i^{\text{cold}}, \text{ek}_i, \text{corrupt} = 0) \in L'_{\text{cold}}$ , where  $\text{ek}_i$  is the value from  $\mathcal{F}_{\text{HC}}$ 's response.

It delivers the response to  $\tilde{P}_i^{\text{cold}}$  once  $\mathcal{A}$  delivers the result of  $\mathcal{F}_{\text{PK}}$  in the internal interaction.

**Client Registration and Share Refreshes** Recall that  $C$  is out of scope for corruptions. Thus, in any case  $\mathcal{S}$  will deliver the message  $(\text{sid}, \text{ClientRegister}, C, (t, \mathcal{I}))$  on  $\tilde{C}$ 's outgoing communication tape to  $\mathcal{F}_{\text{HC}}$  once  $\mathcal{A}$  delivers  $(\text{sid}, \text{SSSetup}, C, (t, \{P_i^{\text{hot}}\}_{i \in [n]}, *))$  from  $C$  to  $\mathcal{F}_{\text{SS}}$  in the internal interaction.  $\mathcal{F}_{\text{HC}}$  will send  $(\text{sid}, \text{ClientRegistered}, C, (\text{vk}))$  to  $\tilde{C}$  and  $(\text{sid}, \text{ClientRegistered}, P_i^{\text{hot}}, (C, b_i))$  to  $\tilde{P}_i^{\text{hot}}$ .  $\mathcal{S}$  delivers these messages to  $\tilde{C}$  and each *honest* party  $\tilde{P}_i^{\text{hot}}$ , respectively, once the corresponding response by  $\mathcal{F}_{\text{SS}}$  is delivered to them in the internal interaction. For any corrupt  $\tilde{P}_i^{\text{hot}}$ ,  $\mathcal{S}$  instead outputs on its behalf the same bit  $b_i$  as  $\mathcal{A}$  does in the internal interaction. The simulation for share refreshes works the same way.

**Signing** We will use the fact that partial BLS signatures  $\sigma_i$  can be verified with respect to the partial verification key  $\text{vk}_i$ . Let  $\text{PVrfy}(\text{vk}_i, m, \sigma_i)$  be the partial verification algorithm, which in the case of BLS consists of checking that  $(g_2, \text{vk}_i, H(m), \sigma_i)$  is a co-Diffie-Hellman tuple (see ??). On input  $(\text{sid}, \text{TSign}, P_i^{\text{hot}}, (C, m))$ , the simulator first delivers the message to  $\mathcal{F}_{\text{HC}}$  once  $\mathcal{A}$  delivers the corresponding request from  $C$  to  $P_i^{\text{hot}}$  in the internal interaction. Then it retrieves the identity of the corresponding  $P_i^{\text{cold}}$  and behaves as follows:

- If  $P_i^{\text{hot}}, P_i^{\text{cold}}$  are both honest,  $\mathcal{S}$  immediately delivers  $\mathcal{F}_{\text{HC}}$ 's output  $(\text{sid}, \text{TSignResult}, P_i^{\text{hot}}, (C, m, \sigma_i))$ .
- If  $P_i^{\text{hot}}$  is honest and  $P_i^{\text{cold}}$  is corrupt,  $\mathcal{S}$  will receive a  $\text{CSignRequest}$  from  $\mathcal{F}_{\text{HC}}$  to which it must respond with a bit  $b$ . It looks at the values  $\sigma_i^{\text{hot}}$  and  $\sigma_i^{\text{cold}*}$  in the internal interaction (the latter is output by  $\mathcal{A}$  on behalf of the corrupt  $P_i^{\text{cold}}$ ) and responds with  $b := \text{PVrfy}(\text{vk}_i, m, \sigma_i^{\text{hot}} / \sigma_i^{\text{cold}*})$ , where  $\text{vk}_i, m$  are the  $i$ th partial verification key and message requested in the *internal* execution (all known to  $\mathcal{S}$ ). As before, it delivers  $\mathcal{F}_{\text{HC}}$ 's output to  $\tilde{C}$  immediately.
- If  $P_i^{\text{hot}}$  is corrupt and  $P_i^{\text{cold}}$  is honest,  $\mathcal{S}$  will receive an  $\text{HSignRequest}$  from  $\mathcal{F}_{\text{HC}}$  to which it must again respond with a bit  $b$ . Similarly, it now looks at the values  $\sigma_i^{\text{hot}*}$  (output by  $\mathcal{A}$ ) and  $\sigma_i^{\text{cold}}$  in the internal execution and responds with  $b := \text{PVrfy}(\text{vk}_i, m, \sigma_i^{\text{hot}*} / \sigma_i^{\text{cold}})$ . Again it immediately delivers  $\mathcal{F}_{\text{HC}}$ 's output to  $\tilde{C}$ .
- Finally, if both  $P_i^{\text{hot}}$  and  $P_i^{\text{cold}}$  are corrupt,  $\mathcal{S}$  checks if  $\text{PVrfy}(\text{vk}_i, m, \sigma_i^{\text{hot}*} / \sigma_i^{\text{cold}*}) = 1$  in the internal execution. If so, it responds 1 to both  $\text{CSignRequest}$  and  $\text{HSignRequest}$ ; otherwise (w.l.o.g.) it sends 0 to both. Then it delivers  $\mathcal{F}_{\text{HC}}$ 's output to  $\tilde{C}$ .

**Proofs of Remembrance** On input  $(\text{sid}, \text{CProof}, C, (P_i^{\text{cold}}))$ , the simulator delivers the message to  $\mathcal{F}_{\text{HC}}$  once  $\mathcal{A}$  delivers the corresponding request from  $C$  to  $P_i^{\text{cold}}$  in the internal interaction.

- If  $\tilde{P}_i^{\text{cold}}$  is honest,  $\mathcal{S}$  delivers  $(\text{sid}, \text{CProofResult}, C, (P_i^{\text{cold}}, b))$  to  $\tilde{C}$  once  $\mathcal{A}$  delivers the output of  $\mathcal{F}_{\text{PK}}$  to  $C$  in the internal execution.

- On the other hand, if  $\tilde{P}_i^{\text{cold}}$  is corrupted,  $\mathcal{S}$  will receive a message from  $\mathcal{F}_{\text{HC}}$  requesting a bit  $b^*$ . It retrieves the party's  $\text{ek}_i$  from  $L'_{\text{cold}}$  and the proof  $\pi_i^{\text{cold}}$  computed by  $\mathcal{A}$  in the internal execution and sends back  $b^* := \Pi_{\text{DL}}.\text{Vrfy}((\text{ek}_i, g_2), \pi_i^{\text{cold}})$ . Finally it delivers  $\mathcal{F}_{\text{HC}}$ 's output  $(\text{sid}, \text{CProofResult}, C, (P_i^{\text{cold}}, b))$  to  $\tilde{C}$  once  $\mathcal{A}$  delivers the message from  $\mathcal{F}_{\text{PK}}$  to  $C$  in the internal execution.

On input  $(\text{sid}, \text{HProof}, P_i^{\text{hot}}, (C))$ ,  $\mathcal{S}$  acts in the same way as  $\text{CProof}$ , except in the corrupted case it sets  $b^* := \Pi_{\text{EKS}}.\text{Vrfy}(\text{com}, \pi_i^{\text{hot}})$ , where both  $\text{com}, \pi_i^{\text{cold}}$  are the party's values in the internal execution.

It is straightforward to see that the simulated registration and share refreshes are identical to a real-world execution. The simulation of the signing protocol is computationally indistinguishable from the real-world execution by the correctness and security of threshold BLS signatures, which guarantees that  $\mathcal{S}$  sends  $b = 1$  iff  $\sigma_i^{\text{cold}*} = H(m)^{\mathcal{H}(\text{vk}^{\text{dk}_i})}$ , resp.  $\sigma_i^{\text{hot}*} = H(m)^{\tilde{x}_i}$ . Similarly, the indistinguishability of simulating proofs of remembrance follows from the correctness and soundness of  $\Pi_{\text{DL}}$  and  $\Pi_{\text{EKS}}$ .  $\square$

Finally, notice that the signing interface of  $\mathcal{F}_{\text{HC}}$  is identical to the functionality offered by threshold BLS, except that  $\mathcal{A}$  additionally learns either  $\sigma_i^{\text{hot}}$  or  $\sigma_i^{\text{cold}}$  (in step 3) or a uniform value  $H(m)^r$  (in step 4). Clearly the uniform value is independent of any private information and can be simulated perfectly as a uniform  $\mathbb{G}_2$  element. As for step 3, the simulator can again send a uniform  $\mathbb{G}_2$  element, now in place of  $\sigma_i^{\text{hot}}$  (alternatively,  $\sigma_i^{\text{cold}}$ ), and the simulation is statistically indistinguishable by Lemma 1.

### 5.7.2 Implementation and Evaluation

We implemented our construction in Rust using the BLS12-381 elliptic curve.<sup>19</sup> Each element in  $\mathbb{G}_1$  is 48 bytes in compressed form,  $\mathbb{G}_2$  is 96 bytes, and  $\mathbb{Z}_p$  is 32 bytes. Thus the sizes of  $\text{vk}$  and  $\text{ek}_i$  are both 96 bytes. The cold and hot shares  $\text{dk}_i$  and  $\tilde{x}_i$ , as well as the share refresh information  $\delta_i$ , are all 32 bytes. The (partial) signatures  $\sigma_i^{\text{hot}}, \sigma_i^{\text{cold}}$ , and  $\sigma_i$ , as well as the commitment  $\text{com}_T$ , are 48 bytes.

We report the runtimes of each of our algorithms for small  $(t, n) = (3, 5)$ , medium  $(5, 20)$ , and large  $(67, 100)$  parameter settings. The times for cold registration and proofs, threshold signing, and processing hot share refreshes (which includes running  $\Pi_{\text{Ref}}.\text{HVerfy}$  to check  $\zeta_i$ ) are all independent of  $(t, n)$  and are shown in Table 7. Hot share generation ( $\text{ClientRegister}$ ), producing hot share refreshes (in our implementation, by  $C$  running the code of  $\mathcal{F}_{\text{SS}}$ ), **Noemi: does this include  $\Pi_{\text{Ref}}.\text{UCVerfy}$ ? i.e., checking that the update is a sharing of zero (verify KZG opening at zero) and that it's degree- $t$  (check  $\text{dcom}$ ). So, it's the bullet of  $\text{ClientUpdate}$  in `spec.tex` that starts with "The system should check that..."** and hot proofs depend on the specific values of  $(t, n)$  and are shown in Table 8. The benchmarks are an average over 1000 runs using a machine with

<sup>19</sup><https://github.com/hyperledger-labs/agora-key-share-proofs/>

8-core AMD Ryzen 9 5900HX with 64GB RAM and cache: L1 512KB, L2 4MB, L3 16 MB at 5GHz. The proof sizes are given in Table 9.

	Time
ColdRegister	360 $\mu$ s
TSign	890 $\mu$ s
ShareRefresh ( $P_i^{\text{hot}}$ )	5ms
Cold Prove ( $\Pi_{\text{DL}}.\text{Prove}$ )	370 $\mu$ s
Cold Verify ( $\Pi_{\text{DL}}.\text{Vrfy}$ )	560 $\mu$ s

Table 7: Benchmarks of our algorithms regardless of threshold

$(t, n) =$	Time (ms)		
	(3, 5)	(5, 20)	(67, 100)
ClientRegister	10	40	170
ShareRefresh ( $C$ )	11	41	172
Hot Prove ( $\Pi_{\text{EKS}}.\text{Prove}$ )	10	40	170
Hot Verify ( $\Pi_{\text{EKS}}.\text{Vrfy}$ )	14	43	4

Table 8: Benchmarks of our algorithms for each setting of  $(t, n)$ . Times for CProof and HProof are not included since they are identical to the corresponding rows of Table 9. The ShareRefresh times for  $C$  and  $P_i^{\text{hot}}$  include the UCVrfy resp. HVrfy times of the refresh proofs in Table 9.

	$ \pi $ (B)
Cold proof ( $\Pi_{\text{DL}}$ )	256
Hot proof ( $\Pi_{\text{EKS}}$ )	304
Refresh proof ( $\zeta_i$ )	48

Table 9: Sizes for our various proof systems regardless of threshold

### 5.7.3 Trustless proactive refresh using a bulletin-board

Recall from Section 5.6.2 that the correctness of our proactive refresh protocols relies on the update polynomial  $z_T(X)$  being of degree  $t - 1 \leq d$  and having  $z_T(0) = 0$ . We can use a folklore technique [CHM<sup>+</sup>20, §2.5] to enforce the degree requirement: the client publishes an additional public “degree commitment”  $\text{dcom}_T := g_1^{\tau^{d-t+1} \cdot z_T(\tau)}$ , which is verified by checking

$$e(\text{dcom}_T, g_2) = e(\text{ucom}_T, g_2^{\tau^{d-t+1}}),$$

where  $d$  is the degree of the KZG CRS. This ensures that the polynomial  $z_T(X)$  committed to by  $\text{ucom}_T$  is of degree at most  $t - 1$ . To enforce the evaluation at zero,  $C$  can simply provide a KZG opening proof for  $\text{ucom}_T$  at  $X = 0$ .

Additionally, the hot parties should also be sure that the client is using the *same* polynomial  $z_T(X)$  for all of them when computing their share updates  $\delta_i$ . This is easily done, since each  $P_i^{\text{hot}}$  is already provided with an evaluation proof  $\zeta_i$  for  $\delta_i$ . In the case of a trusted client, these were assumed to be computed correctly so  $P_i^{\text{hot}}$  only used them to blindly update the its key share and opening proof  $(\tilde{x}_i, \pi_i)$ . In the case of an untrusted client, parties will instead first check their correctness by ensuring  $\text{KZG.Vrfy}(\text{crs}, \text{ucom}_T, i, \delta_i, \zeta_i) = 1$ , and only update their key share and opening proof if verification passes.

Figure 20 gives the proof system  $\Pi_{\text{Ref}}$  used to prove correctness of share refreshes, with verification split between verifying the well-formedness of the update polynomial  $z_T(X)$  committed to by  $\text{ucom}_T$  (via  $\text{UCVrfy}$ ) and of each hot party's refresh information  $\delta_i$  (via  $\text{HVrfy}$ ).

Given  $\Pi_{\text{Ref}}$ , it is fairly simple to realize  $\mathcal{F}_{\text{SS}}$  in a manner that avoids trusting  $C$  except for the setup phase. To do this, we assume a public bulletin board functionality  $\mathcal{F}_{\text{BB}}$  with limited programmability (Figure 21). This functionality will store the most up-to-date commitment  $\text{com}$  to the hot shares  $\tilde{x}_1, \dots, \tilde{x}_n$ . Whenever the shares are refreshed, it will also check the correctness of the update to  $\text{com}$  (namely  $\text{ucom}$ ) before making the new commitment available.

Specifically, instead of only running the steps of  $\mathcal{F}_{\text{SS}}$  locally,  $C$  will compute some additional values using  $\Pi_{\text{Ref}}$  to let  $\mathcal{F}_{\text{BB}}$  and each  $P_i^{\text{hot}}$  check the correctness of the share and update commitments. The proof for the update commitment  $\text{ucom}$  will be checked by  $\mathcal{F}_{\text{BB}}$  before changing the stored commitment. Additionally,  $C$  will let  $\mathcal{F}_{\text{BB}}$  store and distribute  $\text{ucom}$  instead. We describe the full protocol in Figure 22, where changes with respect to locally running the ideal functionality  $\mathcal{F}_{\text{SS}}$  are shown in blue.

**Theorem 7.** *The encrypted secret sharing protocol in Figure 22 UC-realizes  $\mathcal{F}_{\text{SS}}$  in the  $\mathcal{F}_{\text{BB}}$ -hybrid model.*

*Proof.* **todo:** □

## 5.8 Hot-Cold Threshold Schnorr

Next, we show how to adapt FROST [KG20, CKM21, BCK<sup>+</sup>22], a two-round threshold Schnorr protocol, to the hot/cold setting. (Specifically, we use the optimized version, FROST2, introduced in [CKM21].) **Noemi: Justify why FROST (very popular in practice, non-interactive signing phase, security with aborts/concurrency?)**

The idea of our protocol, given in Figure 23, is to let the cold parties generate their pair's nonce commitment  $(D_i, E_i)$  so that only they know the corresponding discrete logarithms  $d_i, e_i$ . This way, given a partial cold signature (where the cold secret is blinded by a function of  $d_i, e_i$ ), a corrupt hot storage is unable to recover the cold secret which would allow it to forge an unlimited number of partial signatures.

Like FROST, our protocol uses two hash functions  $H_1, H_2 : \{0, 1\}^* \rightarrow \mathbb{Z}_q^*$ . During the message-dependent phase, the hot parties help with computing the nonce commitment  $R$  by aggregating every other pair's nonce commitment except their own (we call this incomplete commitment  $R'$ ). The final contribution to  $R$  is added by the cold party itself to ensure that the hot does not replace it with a nonce commitment for which it knows the discrete logarithms. Then it also computes the pair's contribution to the second signature component, namely  $z$ , by using the secret nonce values  $d_i, e_i$ . A blinded version of this component is sent to the hot storage as the cold partial signature. The hot party can use its secret  $s_i^{\text{hot}}$  to unblind it and simultaneously add the pair's secret key share  $\text{sk}_i$ , thereby obtaining  $z_i$ .

Finally, like in the classic FROST protocol, the hot parties broadcast their values  $z_i$  and reconstruct the full signature as  $\sigma := (R, \sum_{i \in SS} z_i) = (g^k, k + c \cdot \text{sk})$ .

**Remark 1.** *The above protocol can be modified in a straightforward manner to FROST1 threshold signatures, the original version of FROST introduced in [KG20].*

### 5.8.1 Security Analysis

We first recall the proof of security for the original FROST2 protocol [BCK<sup>+</sup>22].

**Theorem 8** (informal). *FROST2 is unforgeable assuming the one-more discrete logarithm (OMDL) assumption holds.*

*Proof (informal).* Given an adversary  $\mathcal{A}$  against the unforgeability of FROST2 (specifically, against TS-SUF-2 [BCK<sup>+</sup>22]), we will construct an adversary  $\mathcal{B}$  for the OMDL game. Specifically, given  $2q_s + t$  OMDL challenges  $(A_0, \dots, A_{t-1}, U_1, V_1, \dots, U_{q_s}, V_{q_s})$ ,  $\mathcal{B}$  will output the corresponding discrete logarithms  $(a_0, \dots, a_{t-1}, u_1, v_1, \dots, u_{q_s}, v_{q_s})$  using only  $2q_s + t - 1$  queries to the discrete logarithm oracle  $\text{DLOG}(\cdot)$ .

The idea is as follows:  $\mathcal{B}$  will run  $\mathcal{A}$ , programming the FROST instance with the  $a_j$  as coefficients of the polynomial  $f$  used to share the secret key (that is,  $\text{vk} := A_0 = g^{a_0}$  and  $\text{vk}_i := \prod_{0 \leq j \leq t-1} A_j^{i \cdot j} = g^{f(i)} = g^{\text{sk}_i}$ ) and using the  $(U_k, V_k)$  as preprocessing tokens for FROST partial signatures. Note that this already requires some  $\text{DLOG}(\cdot)$  queries by  $\mathcal{B}$ :  $\mathcal{A}$  receives as input the secret keys of the corrupted parties (the set  $CS$ ), computed as  $\text{sk}_i := \text{DLOG}(\text{vk}_i) \forall i \in CS$ . Computing a partial signature for party  $i$  and signing set  $SS$  using the token  $(U_k, V_k)$  also requires a single query to compute  $z_i := \text{DLOG}(U_k V_k^d \text{vk}_i^{c \lambda_i^{SS}})$ , where  $d, c$  are random oracle outputs.

Once  $\mathcal{A}$  outputs its forgery  $(m^*, \sigma^*)$ , where  $\sigma^* = (R^*, z^*)$  and  $R^*$  was output by the  $I$ th (partial) signing oracle query which also used some preprocessing token  $(U_{k^*}, V_{k^*})$ , we rewind and program different RO outputs for that signing oracle query (and all the following ones as well). By the generalized Forking Lemma [BN06],  $\mathcal{A}$  will still output a forgery on the same message  $m^*$  with a reasonably high probability and now we have two “versions” (forks) of signing oracle queries/responses *with the same preprocessing tokens*  $(U_k, V_k)$ . We can

use this information to extract all of the discrete logarithms with sufficiently few  $\text{DLOG}(\cdot)$  queries.

We will use a tick mark to denote the corresponding variable in the second fork, e.g.,  $\sigma^*$  is the forgery output in the first fork and  $\sigma^{*'}$  in the second. Note that  $\sigma^* = (R^*, z^*)$  and in our simulated FROST2 these will be computed as  $R^* = \prod_{i \in SS} R_i S_i^\rho$  (where each  $(R_i, S_i) = (U_k, V_k)$  for some  $k$ ) and  $z^* = \sum_{i \in SS} \text{DLOG}(R_i S_i^\rho \text{vk}_i^{c \lambda_i^{SS}})$ , where  $\rho, c$  are random oracle outputs. In particular, at exactly the forking point, the second fork will use the same first RO output (so  $\rho' = \rho$  and thus  $R^{*'} = R^*$ ) but a different second RO output (so  $c' \neq c$  and thus  $z^{*'} \neq z^*$ ).

In more detail, to compute  $\text{DLOG}(A_i)$  for all  $i = 0, \dots, t-1$ ,  $\mathcal{B}$  will do the following:

- We have  $g^{z^*} = (\prod_i g^{R_i S_i^\rho}) \cdot \text{vk}^c = R^* A_0^c$  and similarly  $g^{z^{*'}} = R^* A_0^{c'}$ . So,  $g^{z^* - z^{*'}} = g^{a_0(c - c')}$  and we can compute  $a_0 = \frac{z^* - z^{*'}}{c - c'}$ .
- Next, we can look at all the different (honest) parties for which  $\mathcal{A}$  made a partial signing oracle query for  $m^*$  (and the same signing set  $SS^{20}$ ). By the winning condition,  $\mathcal{A}$  can only have made queries for  $< t - |CS|$  honest parties (call this set  $Q^*$ ). For each of those queries, in our simulation we computed  $z_i^*$  by querying  $\text{DLOG}(U_k V_k^\rho \text{vk}_i^{c \lambda_i^{SS}})$  for some  $k$ . So  $g^{z_i^*} = U_k V_k^\rho \text{vk}_i^{c \lambda_i^{SS}}$  and in the second fork  $g^{z_i^{*'}} = U_k V_k^\rho \text{vk}_i^{c' \lambda_i^{SS}}$  and therefore  $g^{z_i^* - z_i^{*'}} = g^{\text{sk}_i(c - c')}$  **Noemi: their paper left out  $\lambda_i^{SS}$  in the exponent.** Now we can solve for  $\text{sk}_i = f(i) = \frac{z_i^* - z_i^{*'}}{c - c'}$  **Noemi: should be divided by  $\lambda_i^{SS}$ .**
- At this point, including the values of  $\text{sk}_i$  queried as inputs to  $\mathcal{A}$ , we have  $|Q^*| + |CS|$  points  $f(i)$  and also  $a_0 = f(0)$ . We will pick some set of indices  $Q'$  of size  $t - |Q^*| - |CS| - 1$  and query  $\text{DLOG}(\text{vk}_j)$  for all  $j \in Q'$  to get  $\text{sk}_j = f(j)$ . Now we have  $t$  evaluations of  $f$ , so we interpolate  $f(X)$  and evaluate at  $X = 1, \dots, t-1$  to get  $a_1, \dots, a_{t-1}$ .

Now we will look more systematically at all the partial signature queries/responses we simulated (at all times beyond just the forking point) to recover  $\text{DLOG}(U_j), \text{DLOG}(V_j)$  for all  $j = 1, \dots, q_s$ . Remember that we issued each  $(U_j, V_j)$  as a preprocessing token, and  $\mathcal{A}$  may or may not have later requested a partial signature using that token. To simplify notation, let  $\text{sk}_i^+ := \text{sk}_i \cdot \lambda_i^{SS}$ .

**Case 0:  $\mathcal{A}$  never requested a signature for that  $(U_j, V_j)$  (in either fork).** In this case we have no information about  $u_j, v_j$  and must request them from the oracle:  $u_j = \text{DLOG}(U_j)$ ,  $v_j = \text{DLOG}(V_j)$ . Note however that this means we didn't have to simulate the partial signature for this token, so we saved a  $\text{DLOG}(\cdot)$  query there.

---

<sup>20</sup>for the case of TS-SUF- $i$  with  $i = 2$ .

**Case 1:  $\mathcal{A}$  only requested a signature for that  $(U_j, V_j)$  in *one* fork.** Because we simulated this partial signature in one fork, we know a value  $z_i = \text{DLOG}(U_j V_j^\rho \text{vk}_i^{c\lambda_i^{SS}})$ . We can compute  $v_j = \text{DLOG}(V_j)$  and  $u_j = z_i - \rho \cdot v_j - c \cdot \text{sk}_i^+$ .

**Case 2:  $\mathcal{A}$  requested a signature for that  $(U_j, V_j)$  in *both* forks.** Because we simulated partial signatures in both forks, we know values  $z_i, z'_i$  such that  $g^{z_i} = U_j V_j^d \text{vk}_i^{c\lambda_i^{SS}}$  and  $g^{z'_i} = U_j V_j^{d'} \text{vk}_{i'}^{c'\lambda_{i'}^{SS}}$ . (Note the preprocessing token  $(U_j, V_j)$  could have been assigned to different parties  $i \neq i'$  in the two forks.) We now have various cases based on whether this request happened before, at, or after the forking point.

- **Case 2a: *after* the forking point.** In this case,  $d \neq d'$  and  $c \neq c'$ . So

$$g^{z_i - z'_i} = g^{v_j(d-d') + \text{sk}_i^+ c - \text{sk}_{i'}^+ c'}. \text{ Therefore we compute } v_j = \frac{z_i - c \cdot f(i) \lambda_i^{SS} - z'_i + c' \cdot f(i') \lambda_{i'}^{SS}}{d - d'}$$

$$\text{and } u_j = z_i - d v_j - c \cdot f(i) \lambda_i^{SS}.$$

- **Case 2b: *at* the forking point.** In this case,  $d = d'$  and  $c \neq c'$  (see above where we calculated the  $a_i$ 's). Here we can learn nothing about  $u_j, v_j$  since their terms are the same in both forks, so we have to resort to the same strategy as Case 1 and compute  $v_j = \text{DLOG}(V_j)$  and

$$u_j = z_i - d v_j - c \cdot \text{sk}_i^+.$$

- **Case 2c: *before* the forking point.** In this case,  $d = d'$  and  $c = c'$  and again we have no information about  $u_j, v_j$  and compute  $v_j = \text{DLOG}(V_j)$  and  $u_j = z_i - d v_j - c \cdot \text{sk}_i^+$  as in Case 1 (and 2b). Note that for simulating the partial signature, we were able to reuse the outputs from the first fork in the second, so as in Case 0 we save a  $\text{DLOG}(\cdot)$  query.

Clearly we have now calculated all  $2q_s + t$  discrete logarithms correctly, so it remains to show that we only used  $2q_s + t - 1$   $\text{DLOG}(\cdot)$  queries to do it:

- $|CS|$  to compute the inputs  $\{\text{sk}_i\}_{i \in CS}$  to  $\mathcal{A}$ ,
- $|Q'|$  to compute  $a_0, \dots, a_{t-1}$ ,
- 2 total for each  $j = 1, \dots, q_s$  to compute  $u_j, v_j$  and/or to simulate the partial signature for  $U_j, V_j$ —except for Case 2b, where we have to simulate partial signatures (each for some party  $i$ ) for  $U_j, V_j$  in both forks *at* the forking point (i.e., on the winning message  $m^*$ ). Remember that these were requested for parties in the set  $Q^*$ , so we only have to make  $|Q^*| < t - |CS|$  (by the winning condition) queries  $\text{DLOG}(V_j)$  (i.e., only  $|Q^*|$  values of  $j$  fall under Case 2b).

In total, the number of  $\text{DLOG}(\cdot)$  queries is  $|CS| + |Q'| + 2q_s + |Q^*|$ , and since  $|Q'| = t - |Q^*| - |CS| - 1$  and  $|CS| < t$  (by the winning condition of unforgeability) this is equal to  $2q_s + t - 1$  queries.

Finally, we need to argue about the advantage of  $\mathcal{B}$  assuming  $\mathcal{A}$  has non-negligible advantage. There are two events (called **BadPPO** and **BadHash** in [BCK<sup>+</sup>22]) in which  $\mathcal{B}$  will fail even though  $\mathcal{A}$  wins (resp. either by failing to simulate FROST to  $\mathcal{A}$  or by having colliding RO outputs when forking/rewinding  $\mathcal{A}$ ). Let  $\mathcal{C}$  denote the subroutine of  $\mathcal{B}$  dedicated to simulating FROST ( $\mathcal{C}$  “accepts”, i.e.,  $\text{acc}(\mathcal{C}) = 1$ , if it does so successfully and  $\mathcal{A}$  wins):

$$\Pr[\text{acc}(\mathcal{C})] \geq \Pr[\text{Adv}(\mathcal{A})] - \Pr[\text{BadPPO}]$$

By a variant of the Forking Lemma [BCK<sup>+</sup>22, Lemma 5.3],

$$\Pr[\text{Adv}(\mathcal{B})] \geq \text{acc}(\mathcal{C})^2/q - \Pr[\text{BadHash}]$$

where  $q$  is the number of RO queries in  $\mathcal{C}$  (equal to  $q_s + q_h + 1$ , where  $q_s$  is the number of partial signature queries and  $q_h$  is the number of any other RO queries  $\mathcal{A}$  makes). **Noemi: idk where +1 comes from**

By the bounds on  $\Pr[\text{BadPPO}]$  and  $\Pr[\text{BadHash}]$  (see [BCK<sup>+</sup>22]), we end up with

$$\Pr[\text{Adv}(\mathcal{B})] \geq \Pr[\text{Adv}(\mathcal{A})]^2/q - 3q^2/p.$$

So the existence of an adversary  $\mathcal{A}$  with non-negligible advantage in the TS-SUF-2 game implies an adversary  $\mathcal{B}$  with non-negligible advantage in the OMDL game, which contradicts our assumption.  $\square$

We now show how to modify the above proof to show that the protocol in Figure 23 is HC-SUF-2-secure. For readability, in Figure 24 we give a version of the unforgeability oracles which is tailored to HC-FROST2.

**Theorem 9.** *The hot/cold variant of FROST2 described in ?? is unforgeable assuming OMDL.*

*Proof (sketch).* The idea is for the reduction to program the OMDL challenges into the inputs to  $\mathcal{A}$  like before. So, the  $\text{vk}, \text{vk}_1, \dots, \text{vk}_n$  will encode the challenges  $A_0, \dots, A_{t-1}$ . For  $\mathcal{A}$ ’s inputs, for  $i \in CS_{\text{hot}} \cap CS_{\text{cold}}$ , the reduction samples  $\Delta_i \xleftarrow{\$} \mathbb{Z}_q$ , computes  $\text{sk}_i \leftarrow \text{DLOG}(\text{vk}_i)$ , and sets  $s_i^{\text{cold}} = \Delta_i$ ,  $s_i^{\text{hot}} = \text{sk}_i + \Delta_i$ ; for  $i \in CS_{\text{hot}} \setminus CS_{\text{cold}}$ , it lets  $s_i^{\text{hot}} \xleftarrow{\$} \mathbb{Z}_q$ , and similarly for  $i \in CS_{\text{cold}} \setminus CS_{\text{hot}}$ , it lets  $s_i^{\text{cold}} \xleftarrow{\$} \mathbb{Z}_q$ .

The reduction will answer PSIGNO queries as before using the challenges  $(U_k, V_k)$ . It also handles RO queries like before. Previously, partial signature queries were answered by querying the discrete log oracle once to get  $z_i \leftarrow \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}})$ . Now we have to instead handle queries to CSIGNO and HSIGNO, but we will do it again with a single DLOG query *per pair*. In CSIGNO( $i, \cdot$ ) (only answered if  $P_i^{\text{cold}}$  is honest), if  $P_i^{\text{hot}}$  is honest we sample  $r \xleftarrow{\$} \mathbb{Z}_q$  and compute  $z_i^{\text{cold}} = \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}}) - c \cdot r \cdot \lambda_i^{SS}$ , otherwise  $z_i^{\text{cold}} = \text{DLOG}(U_k V_k^\rho) - c \cdot s_i^{\text{hot}} \lambda_i^{SS}$ . For HSIGNO( $i, \sigma_i^{\text{cold}}$ ) (similarly only answered if  $P_i^{\text{hot}}$  is honest), if  $P_i^{\text{cold}}$  is honest we compute  $z_i = \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}})$ , where

we can reuse the output of a potential previous DLOG query in CSIGNO on the same value. Otherwise  $z_i = \text{DLOG}(\text{vk}_i^{c\lambda_i^{SS}}) + \sigma_i^{\text{cold}} + c\Delta_i\lambda_i^{SS}$ .

Given a successful forgery by  $\mathcal{A}$ , computing the discrete logarithms to the OMDL challenges is similar. As before,  $a_0 = \frac{z^* - z'^*}{c - c'}$ . Then, for every query to either CSIGNO or HSIGNO we can recover a point  $f(i)$  as follows:

**case 1:  $\mathcal{A}$  queried HSIGNO( $i, \cdot$ ) and  $i \in HS_{\text{cold}}$ .** That means we have two values  $z_i, z'_i$  from the two forks such that  $g^{z_i} = U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}}$  and  $g^{z'_i} = U_k V_k^\rho \text{vk}_i^{c'\lambda_i^{SS}}$  and therefore  $g^{z_i - z'_i} = g^{\text{sk}_i \lambda_i^{SS}(c - c')}$ . Then  $\text{sk}_i = f(i) = \frac{z_i - z'_i}{\lambda_i^{SS}(c - c')}$ .

**case 2:  $\mathcal{A}$  queried HSIGNO( $i, \cdot$ ) and  $i \notin HS_{\text{cold}}$ .** Then the response  $z_i$  was instead computed as  $z_i = \text{DLOG}(\text{vk}_i^{c\lambda_i^{SS}}) + z_i^{\text{cold}} + c\Delta_i\lambda_i^{SS}$ . Thus, **todo: assuming (forking lemma?) that  $\mathcal{A}$  queried on the same  $z_i^{\text{cold}}$**  from the two forks we have values  $z_i, z'_i$  such that  $g^{z_i - z'_i} = g^{(\text{sk}_i + \Delta_i)\lambda_i^{SS}(c - c')}$ . Then  $\text{sk}_i = f(i) = \frac{z_i - z'_i}{\lambda_i^{SS}(c - c')} - \Delta_i$ , where the value  $\Delta_i$  was sampled as an input for  $\mathcal{A}$  so it is known to the reduction.

**case 3:  $\mathcal{A}$  queried CSIGNO( $i, \cdot$ ) and  $i \notin HS_{\text{hot}}$ .** Here the response is computed as  $z_i^{\text{cold}} = \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}}) - c \cdot s_i^{\text{hot}} \lambda_i^{SS}$ . Given the responses from the two forks, we have  $z_i^{\text{cold}}, z_i^{\text{cold}'}$  such that  $g^{z_i^{\text{cold}} - z_i^{\text{cold}'}} = g^{(\text{sk}_i - s_i^{\text{hot}})\lambda_i^{SS}(c - c')}$  and can compute  $\text{sk}_i = f(i) = \frac{z_i^{\text{cold}} - z_i^{\text{cold}'}}{\lambda_i^{SS}(c - c')} + s_i^{\text{hot}}$ , where the value  $s_i^{\text{hot}}$  was sampled as an input for  $\mathcal{A}$  so it is known to the reduction.

**case 4:  $\mathcal{A}$  queried CSIGNO( $i, \cdot$ ) and  $i \in HS_{\text{HS}}$ , and  $\mathcal{A}$  did not query HSIGNO( $i, \cdot$ ).**

(Note that if  $\mathcal{A}$  *did* query HSIGNO( $i, \cdot$ ), this falls under case 1 instead.)

Now we have values  $z_i^{\text{cold}} = \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c\lambda_i^{SS}}) - c \cdot r_i \lambda_i^{SS}$  and  $z_i^{\text{cold}'} = \text{DLOG}(U_k V_k^\rho \text{vk}_i^{c'\lambda_i^{SS}}) - c' r_i \lambda_i^{SS}$ , where we use the same random coins for  $r_i$  in both forks. Therefore we compute  $\text{sk}_i = f(i) = \frac{z_i^{\text{cold}} - z_i^{\text{cold}'}}{(c - c')\lambda_i^{SS}} + r_i$ .

Recall that these queries are captured by the set  $Q^* = (S_{\text{hot}}(lr) \cap CS_{\text{cold}}) \cup (CS_{\text{hot}} \cap S_{\text{cold}}(lr)) \cup (S_{\text{hot}}(lr) \cap S_{\text{cold}}(lr))$ . Along with  $a_0 = f(0)$  and the values of  $\text{sk}_i$  we queried as inputs to  $\mathcal{A}$ , we now have  $|Q^*| + |CS_{\text{hot}} \cap CS_{\text{cold}}| + 1$  evaluations of the polynomial  $f$ . As in the previous proof, next we pick a set  $Q'$  of indices, where  $|Q'| = t - |Q^*| - 1$ , and query  $\text{sk}_j = f(j) = \text{DLOG}(\text{vk}_j)$  for  $j \in Q'$ . This gives us a total of  $t$  evaluations of  $f$ , allowing us to recover all the remaining values  $a_1, \dots, a_{t-1}$ .

To compute the discrete logarithms of the challenges  $(U_1, V_1), \dots, (U_{q_s}, V_{q_s})$ , we can use the same approach as before, unmodified. Anytime  $\mathcal{A}$  requested a signature using some token  $(U_j, V_j)$  **todo: except HSIGNO with corrupt cold, need to figure that out...**, we know a value  $z_i = \text{DLOG}(U_j V_j^\rho \text{vk}_i^{c\lambda_i^{SS}})$  and the same case analysis applies.

It remains to count the DLOG( $\cdot$ ) queries used:

- $|CS_{\text{hot}} \cap CS_{\text{cold}}|$  for  $\mathcal{A}$ 's inputs,
- $|Q'|$  to compute  $a_0, \dots, a_{t-1}$ , and
- $2q_s + |Q^*|$  to compute  $u_j, v_j$  and/or simulate the partial signature(s) for  $U_j, V_j$ .

Remember that  $|Q'| = t - |Q^*| - |CS_{\text{hot}} \cap CS_{\text{cold}}| - 1$ , so once again the total number of DLOG queries used by the reduction is  $2q_s + t - 1$ . □

## 6 Conclusion

We described three examples of how advanced cryptography can improve the security and trust assumptions of blockchain applications in a practical and deployable manner: naysayer proofs, the Cicada voting and auction framework, and hot-cold threshold wallets. While these works have had significant industry discussion and/or collaboration, it is my hope that they will also see practical deployment in the near future.

The ideas discussed in this dissertation also have significant potential to spark additional discussion and future work. The naysayer paradigm can be substituted for classic zero-knowledge proofs in any application which uses the latter as a building block. A more theoretical analysis of their complexity, lower bounds, and application to particular classes of underlying verifier circuits may also be fruitful. There is also room for optimizing naysayer provers to particular underlying proof systems. Finally, like optimistic rollups, naysayer proofs would benefit from a rigorous analysis of how to set collateral and delay periods in optimistic settings.

We have shown that the Cicada framework is a useful blueprint for fair on-chain elections and auctions and have shown its practicality for many popular protocols. Extending Cicada to other, non-additive protocols could be a useful future work. Additionally, each of the proposed extensions can be explored in greater detail as well.

Finally, our hot-cold threshold wallet protocols cover two popular threshold signature schemes used in the blockchain ecosystem today, but it may be desirable or necessary to extend other threshold signatures to this setting. Furthermore, although our protocols already offer several advanced functionalities, deployments may wish to extend our protocols more, e.g., by adding distributed key generation, hot share refreshes, and secret resharing.

Cryptography has seen significant deployment in the blockchain ecosystem and driven some of its most important innovations. As the space continues to grow, cryptographic protocols and primitives have a large role to play in furthering security, decentralization, and scalability.

**Construction 1** (Linear HTLP [MT19]).

HTLP.Setup( $1^\lambda, T$ )  $\xrightarrow{\$}$  pp. Sample a strong semiprime  $N$  and a generator  $g \xleftarrow{\$} \mathbb{Z}_N^*$ , then compute  $h = g^{2^T} \bmod N \in \mathbb{Z}_N^*$ . (This can be computed efficiently using the factorization of  $N$ ). Output  $\text{pp} := (N, g, h)$ .

HTLP.Gen(pp,  $s; r$ )  $\rightarrow Z$ . Given a value  $s \in \mathbb{Z}_N$ , use randomness  $r \in \mathbb{Z}_{N^2}$  to compute and output

$$Z := (g^r \bmod N, h^{r \cdot N} \cdot (1 + N)^s \bmod N^2) \in \mathbb{J}_N \times \mathbb{Z}_{N^2}^*$$

HTLP.Open(pp,  $Z, r$ )  $\rightarrow s$ . Parse  $Z := (u, v)$  and compute  $w := u^{2^T} \bmod N = h^r$  via repeated squaring. Output  $s := \frac{(v/w^N \bmod N^2) - 1}{N}$ .

HTLP.Eval(pp,  $f, Z_1, Z_2$ )  $\rightarrow Z$ . To evaluate a linear function  $f(x_1, x_2) = b + a_1x_1 + a_2x_2$  homomorphically on puzzles  $Z_1 := (u_1, v_1)$  and  $Z_2 := (u_2, v_2)$ , return

$$Z = (u_1^{a_1} \cdot u_2^{a_2} \bmod N, v_1^{a_1} \cdot v_2^{a_2} \cdot (1 + N)^b \bmod N^2).$$

**Construction 2** (Multiplicative HTLP [MT19]).

HTLP.Setup( $1^\lambda, T$ )  $\xrightarrow{\$}$  pp. Same as construction 1.

HTLP.Gen(pp,  $s; r$ )  $\rightarrow Z$ . Given a value  $s \in \mathbb{J}_N$ , use randomness  $r \in \mathbb{Z}_{N^2}$  to compute and output

$$Z := (g^r \bmod N, h^r \cdot s \bmod N) \in \mathbb{Z}_N^* \times \mathbb{Z}_N^*$$

HTLP.Open(pp,  $Z, r$ )  $\rightarrow s$ . Parse  $Z := (u, v)$  and compute  $w := u^{2^T} \bmod N = h^r$  via repeated squaring. Output  $s := v/w$ .

HTLP.Eval(pp,  $f, Z_1, Z_2$ )  $\rightarrow Z$ . To evaluate a multiplicative function  $f(x_1, x_2) = ax_1x_2$  homomorphically on puzzles  $Z_1 := (u_1, v_1)$  and  $Z_2 := (u_2, v_2)$ , return

$$Z = (u_1 \cdot u_2 \bmod N, a \cdot v_1 \cdot v_2 \bmod N)$$

Figure 1: The HTLP constructions of [MT19].

Figure 2: The proof system  $\Pi_{\text{ped}}$  used to prove knowledge of the opening to a Pedersen commitment [Oka93].

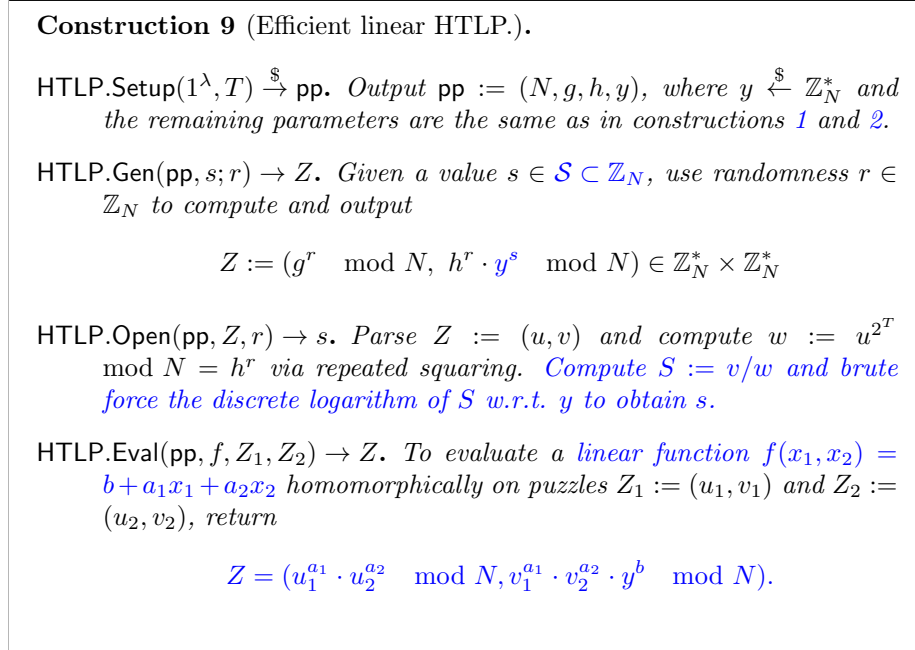

Figure 3: Efficient linear HTLP for small solution space.

Figure 4: Our model of an HTLP-based auction/voting scheme. (1) *Submission phase*: users generate their bids/ballots as HTLPs and post them to a public bulletin board, e.g., a blockchain. (2) *Aggregation*: an on-chain contract homomorphically combines submissions into a single aggregate puzzle. (3) *Opening*: after the submissions have been aggregated, an off-chain entity solves the aggregate HTLP using  $T$  sequential steps and submits the solution to the contract. (4) *Finalize*: The smart contract may do some final computation over the solution to compute the result and announces the winner. Submission privacy is ensured only until the start of the **Open** phase. In Section 4.10.1, we show how voters can optionally achieve everlasting ballot privacy.

### The Cicada Framework

Let  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  be the scoring function of a voting/auction scheme where  $\Sigma = f \circ t$  for a linear function  $t$  and  $\mathcal{X} = [0, w]^m$ . Let HTLP a linear HTLP,  $T \in \mathbb{N}$  a time parameter representing the election/auction length, and (PSetup, Pack, Unpack) a packing scheme. Let NIZK be a NIZKPoK for submission correctness (language depends on  $\Sigma$ , HTLP; see Section 4.7) and PoS be a proof of correct HTLP solution (see Section 4.7).

---

Setup( $1^\lambda, T, \ell$ )  $\xrightarrow{\$}$  (pp,  $\mathcal{Z}$ ). Set up the public parameters  $\text{pp}_{\text{NIZK}} \xleftarrow{\$}$  NIZK.Setup( $1^\lambda$ ),  $\text{pp}_{\text{tlp}} \xleftarrow{\$}$  HTLP.Setup( $1^\lambda, T$ ), and  $\text{pp}_{\text{pack}} \leftarrow$  PSetup( $\ell, w$ ). Let  $\mathcal{Z} = \{Z_j\}_{j \in [m/\ell]}$  where  $Z_j \xleftarrow{\$}$  HTLP.Gen(0). Output  $\text{pp} := (\text{pp}_{\text{tlp}}, \text{pp}_{\text{pack}}, \text{pp}_{\text{NIZK}})$  and  $\mathcal{Z}$ .

Seal(pp,  $i, \mathbf{v}_i$ )  $\xrightarrow{\$}$  ( $\mathcal{Z}_i, \pi_i$ ). Parse  $\mathbf{v}_i := \mathbf{v}_{i,1} || \dots || \mathbf{v}_{i,m/\ell}$ . Compute  $Z_{i,j} \leftarrow$  HTLP.Gen(Pack( $\mathbf{v}_{i,j}$ ))  $\forall j \in [m/\ell]$  and  $\pi_i \leftarrow$  NIZK.Prove( $(i, \mathcal{Z}_i), \mathbf{v}_i$ ). Output ( $\mathcal{Z}_i := \{Z_{i,j}\}_{j \in [m/\ell]}, \pi_i$ )

Aggr(pp,  $\mathcal{Z}, i, \mathcal{Z}_i, \pi_i$ )  $\rightarrow \mathcal{Z}'$ . If NIZK.Vrfy( $(i, \mathcal{Z}_i), \pi_i$ ) = 1, update  $\mathcal{Z}$  to  $\mathcal{Z} \boxplus \mathcal{Z}_i$ .

Open(pp,  $\mathcal{Z}$ )  $\rightarrow (\mathcal{S}, \pi_{\text{open}})$ . Parse  $\mathcal{Z} := \{Z_j\}_{j \in [m/\ell]}$  and solve for the encoded tally  $\mathcal{S} = \{s_j\}_{j \in [m/\ell]}$  where  $s_j \leftarrow$  HTLP.Solve( $Z_j$ ). Prove the correctness of the solution(s) as  $\pi_{\text{open}} \leftarrow$  PoS.Prove( $\mathcal{S}, \mathcal{Z}, 2^T$ ) and output  $(\mathcal{S}, \pi_{\text{open}})$ .

Finalize(pp,  $\mathcal{Z}, \mathcal{S}, \pi_{\text{open}})$   $\rightarrow \{y, \perp\}$ . If PoS.Verify( $\mathcal{S}, \mathcal{Z}, 2^T, \pi_{\text{open}}$ )  $\neq 1$ , return  $\perp$ . Otherwise, parse  $\mathcal{S} := \{s_j\}_{j \in [m/\ell]}$  and let  $\mathbf{v} := \mathbf{v}_1 || \dots || \mathbf{v}_{m/\ell}$ , where  $\mathbf{v}_j \leftarrow$  Unpack( $s_j$ )  $\forall j \in [m/\ell]$ . Output  $y$  such that  $y = \Sigma(\mathbf{v})$ .

Figure 5: The Cicada framework for non-interactive private auctions and elections.

### Borda ballot correctness

**todo: incomplete**

1.  $\mathcal{P}$  sends  $(g^a \bmod N, (1 + N)^a \bmod N^2)$  for  $a \xleftarrow{\$} \mathbb{Z}_N$ .
2.  $\mathcal{V}$  sends a challenge  $e \xleftarrow{\$} [1, n]$ .
3.  $\mathcal{P}$  sends  $(g^{r \cdot e + a}, h^{r \cdot N \cdot e + a} (1 + N)^{s \cdot e + a} \bmod N^2)$ .  $\mathcal{V}$  accepts iff the following hold:

Figure 6: Most efficient HTLP construction for voting and auction using Cicada with maximal packing (using PNS except where indicated).

Figure 7: Most efficient HTLP construction for voting schemes using Cicada without packing. For the sealed-bid auction, the bid bit-length directly determines the HTLP construction to use (exponential ElGamal up to 80 bits, then Paillier up to 2048, and class group up to 3400).

### Off-chain batching

**Public parameters:** A semiprime  $N$  and  $h, y \in \mathbb{Z}_N^*$ , a voting scheme  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$ .

Let  $P_1, \dots, P_k$  be a group of  $k < n$  parties with addresses  $\text{addr}_1, \dots, \text{addr}_k$  wishing to batch their ballots  $(u_i, v_i) := (g^{r_i}, h^{r_i} X_i)$ .

1. Each party broadcasts  $v_i$ . Now, every party can compute  $v := \prod_i v_i = h^R X$ , which encodes the sum of their submissions.
2. The parties use an  $k - 1$  malicious-secure MPC protocol [DKL<sup>+</sup>13, Kel20] on inputs  $u_i$  to compute  $u := \prod_i u_i = g^R$ .
3. They also compute two distributed-prover zero-knowledge proofs [DPP<sup>+</sup>22] in the MPC: (i) a discrete logarithm equality proof  $\pi_R$  that  $\text{dlog}_g(u) = \text{dlog}_h(v)$  with distributed witness  $R$ , and (ii) a submission correctness proof  $\pi_s$  that the aggregated solution  $s$  encoded in  $X$  is consistent with the sum of  $k$  valid submissions, i.e.,  $s \in k \cdot \mathcal{X}$ . Let  $\pi_{\text{batch}} = (\pi_R, \pi_s)$ .
4. Finally, each party signs the final aggregated submission  $Z_{\text{batch}} = (u, v)$ .

**Output:**  $(Z_{\text{batch}}, \pi_{\text{batch}}, \{\text{addr}_1, \dots, \text{addr}_k\}, \{\sigma_1, \dots, \sigma_k\})$ .

### On-chain batched ballot submission

**Public parameters:** Cicada public parameters  $\text{pp}$ .

1. The designated party  $P_1$  submits  $Z_{\text{batch}}, \pi_{\text{batch}}, \{\text{addr}_1, \dots, \text{addr}_k\}, \{\sigma_1, \dots, \sigma_k\}$  to the tallying contract, which verifies the proofs and signatures, and adds  $(u, v)$  to the tally HTLP  $Z$  as in the basic protocol.
2. If  $P_1$  doesn't submit by time  $T - \tau$ , any other party in the batch group can submit instead.

Figure 8: The on- and off-chain ballot batching protocols that  $k < n$  parties can use to achieve everlasting ballot privacy.

### Borda ballot correctness

todo: incomplete

1.  $\mathcal{P}$  sends  $(g^a \bmod N, (1 + N)^a \bmod N^2)$  for  $a \xleftarrow{\$} \mathbb{Z}_N$ .
2.  $\mathcal{V}$  sends a challenge  $e \xleftarrow{\$} [1, n]$ .
3.  $\mathcal{P}$  sends  $(g^{r \cdot e + a}, h^{r \cdot N \cdot e + a} (1 + N)^{s \cdot e + a} \bmod N^2)$ .  $\mathcal{V}$  accepts iff the following hold:

### Preprocessing ballots for succinct ballot-correctness proofs

**Public parameters:** The common reference string  $\text{crs} := \{g_1^{r^j}\}_{j=1}^d \in \mathbb{G}_1^d$ . A semiprime  $N$  and  $h, y \in \mathbb{Z}_N^*$ . A voting scheme  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$ , e.g., approval voting.

1. Let  $\mathcal{X}$  be the set of correct ballots and  $|\mathcal{X}| = d$
2. Let  $f(x) \in \mathbb{F}_p^{\leq d}[x]$  be a univariate polynomial s.t.  $\forall s_i \in \mathcal{X} : f(i) := \text{Pack}(s_i)$ . The polynomial  $f(x)$  could be computed using Lagrangian interpolation.
3. Let  $\text{com}$  be the KZG commitment to the polynomial  $f$ .

**Output:**  $\text{com}$ .

Figure 9: Preprocessing ballots to enable succinct ballot-correctness proofs.

### The CJSS Framework

Let  $\Pi_E$  be a CCA-secure public-key encryption scheme, TLP a time-lock puzzle scheme, and  $\Sigma : \mathcal{X}^n \rightarrow \mathcal{Y}$  a base voting/auction protocol.

**Setup** $(1^\lambda, T) \xrightarrow{\S} (\text{pp}, \mathcal{Z})$ . Sample a key-pair  $(\text{pk}, \text{sk}) \leftarrow \Pi_E.\text{Gen}(1^\lambda)$  and TLP parameters  $\text{pp}_{\text{tlp}} \leftarrow \text{TLP.Setup}(1^\lambda, T)$ . Compute  $Z_{\text{sk}} \xleftarrow{\S} \text{TLP.Gen}(\text{pp}_{\text{tlp}}, \text{sk})$  and return  $\text{pp} := (\text{pp}_{\text{tlp}}, \text{pk})$  and  $\mathcal{Z} := (Z_{\text{sk}}, \perp)$ .

**Seal** $(\text{pp}, i, s) \xrightarrow{\S} (\text{ct}_i, \pi_i)$ . Parse  $\text{pk}$  from  $\text{pp}$  and compute an encrypted bid/ballot as  $\text{ct}_i \leftarrow \Pi_E.\text{Enc}(\text{pk}, s_i)$  along with a proof  $\pi_i$  that  $\text{ct}_i$  is a valid encryption under  $\text{pk}$ .

**Aggr** $(\text{pp}, \mathcal{Z}, \text{ct}_i, \pi_i) \rightarrow \mathcal{Z}'$ . Verify  $\pi_i$ . If the check passes, parse  $\mathcal{Z} := (Z_{\text{sk}}, \mathcal{C})$  and update to  $\mathcal{Z}' := (Z_{\text{sk}}, \mathcal{C} \cup \{\text{ct}_i\})$ .

**Open** $(\text{pp}, \mathcal{Z}, \perp) \rightarrow \text{sk}$ . Let  $\mathcal{Z} := (Z_{\text{sk}}, \mathcal{C})$  and publish  $\text{sk} \leftarrow \text{HTLP.Solve}(\text{pp}_{\text{tlp}}, Z_{\text{sk}})$ .

**Finalize** $(\text{pp}, \text{sk}) \rightarrow y$ . Use the secret key  $\text{sk}$  to decrypt each ciphertext  $\text{ct}_i \in \mathcal{C}$  to  $s_i \leftarrow \Pi_E.\text{Dec}(\text{sk}, \text{ct}_i)$ . Compute the final result in the clear as  $\Sigma(s_1, \dots, s_n)$ .

Figure 10: The “solve one, get many for free” paradigm (CJSS) [CJSS21].

Figure 11: A hot-cold threshold wallet with  $n = 3$ . Given a message  $m$ , each  $P_i^{\text{cold}}$  uses its cold share  $\text{sk}_i^{\text{cold}}$  to compute a cold partial signature  $\sigma_i^{\text{cold}}$  on  $m$  and sends it to its hot storage.  $P_i^{\text{hot}}$  uses  $m$  and its hot share  $\text{sk}_i^{\text{hot}}$  to compute  $\sigma_i^{\text{hot}}$ , which it combines with  $\sigma_i^{\text{cold}}$  to get  $\sigma_i$ . The hot parties broadcast their partial signatures to each other to reconstruct the full signature  $\sigma$  on  $m$ . The dashed lines between each cold and hot storage represent the authenticated channel between them which is only active at signing time. The hot parties are always online and connected, represented by the solid lines.

### HOT STORAGE PROOFS OF ENCRYPTED KEY SHARE ( $\Pi_{\text{EKS}}$ )

**Parameters:** Generators  $g_1, h_1 \in \mathbb{G}_1$  and  $g_2 \in \mathbb{G}_2$ ; a degree- $d$  KZG common reference string  $\text{crs} = \{g_1, g_1^\tau, \dots, g_1^{\tau^d}, g_2, g_2^\tau\}$ .

$\text{Prove}((\text{crs}, \text{com}_T, i); (\tilde{x}_i, \pi_{T,i})) \rightarrow \pi_i^{\text{hot}}$ : Given  $\text{crs}$ , a KZG commitment  $\text{com}_T$  to the current polynomial  $\tilde{f}_T(X)$ , and its index  $i$ , a hot storage uses its key share  $\tilde{x}_i = \tilde{f}_T(i)$  and corresponding opening proof  $\pi_{T,i}$  to compute a ZKPoK of  $\tilde{x}_i$  as follows:

1. Sample  $r \xleftarrow{\$} \mathbb{Z}_p$ , let  $\text{com}_{\text{ped}} := g_1^{\tilde{x}_i} h_1^r$ , and compute  $\pi_{\text{ped}} \leftarrow \Pi_{\text{ped}}.\text{Prove}(\text{com}_{\text{ped}}; (\tilde{x}_i, r))$  (see Section 2.9).
2. Sample  $s \xleftarrow{\$} \mathbb{Z}_p$  and let  $s_i(X) := -r - s(X - i)$ . Compute  $\bar{\pi}_{T,i} := \pi_{T,i} h_1^s$  and  $S := g_2^{s_i(\tau)}$  using  $\text{crs}$ .
3. Output  $\pi_i^{\text{hot}} := (\text{com}_{\text{ped}}, \pi_{\text{ped}}, \bar{\pi}_{T,i}, S)$ .

$\text{Vrfy}((\text{crs}, \text{com}_T, i), \pi_i^{\text{hot}}) \rightarrow \{0, 1\}$ : Given  $\text{crs}$ , a KZG commitment  $\text{com}_T$ , and a party index  $i$ , verify the hot storage proof  $\pi_i^{\text{hot}} = (\text{com}_{\text{ped}}, \pi_{\text{ped}}, \bar{\pi}_{T,i}, S)$  by outputting 1 iff the following hold:

$$\begin{aligned} \Pi_{\text{ped}}.\text{Vrfy}(\text{com}_{\text{ped}}, \pi_{\text{ped}}) &= 1 \\ e(\text{com}_T / \text{com}_{\text{ped}}, g_2) &= e(\bar{\pi}_{T,i}, g_2^\tau / g_2^i) \cdot e(h_1, S). \end{aligned}$$

Figure 12: The proof system  $\Pi_{\text{EKS}}$  used by each  $P_i^{\text{hot}}$  to show possession of a valid encrypted key share with respect to the current KZG commitment.

**Public parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of prime order  $p$  with generators  $g_1, g_2$ , respectively; a degree- $d$  KZG common reference string  $\text{crs}$ .

- On input  $(\text{sid}, \text{SSSetup}, C, (t, \mathcal{P}, \{\text{ek}_i\}_{i \in [n]}))$ , where  $\mathcal{P} = \{P_1, \dots, P_n\}$  is a set of parties, for  $i \in [n]$ ,  $\text{ek}_i \in \mathbb{G}_2$  is an encryption key, and  $t \leq |\mathcal{P}|$ , it proceeds as follows:
  1. Sample  $x \xleftarrow{\$} \mathbb{Z}_p \setminus \{0\}$ . Let  $y := g_2^x$ .
  2. Generate  $t$ -out-of- $n$  Shamir Shares of  $x$  as  $x_1, \dots, x_n \in \mathbb{Z}_p$ . Let  $y_i := g_2^{x_i} \forall i \in [n]$ .
  3. Interpolate the degree- $n$  polynomial  $\tilde{f}$  such that  $\tilde{f}(i) = \mathcal{H}(\text{ek}_i^x) + x_i \forall i \in [n]$ . Compute  $\text{com} \leftarrow \text{KZG.Com}(\text{crs}, \tilde{f})$ .
  4. Delete any entries  $(C, *, *, *, *, *) \in D$ . Add  $(C, \mathcal{P}, t, y, \text{com}, \text{time} := 1)$  to  $D$ .
  5. For each  $i \in [n]$ , compute  $(\tilde{x}_i, \pi_i) \leftarrow \text{KZG.Open}(\text{crs}, \tilde{f}, i)$  and output  $(\text{sid}, \text{SecretShare}, P_i, (C, i, \tilde{x}_i, \pi_i))$ .
  6. Finally, output  $(\text{sid}, \text{SSSetupDone}, C, (y, \{y_i\}_{i \in [n]}))$ .
- On input  $(\text{sid}, \text{ZeroSetup}, C, (t, \mathcal{P}))$ , where  $\mathcal{P} = \{P_1, \dots, P_n\}$  is a set of parties and  $t \leq |\mathcal{P}|$ , it proceeds as follows:
  1. Generate  $t$ -out-of- $n$  Shamir Shares of 0 as  $x_1, \dots, x_n \in \mathbb{Z}_p$ ; let  $f$  be the polynomial used.
  2. Compute  $\text{com}_0 \leftarrow \text{KZG.Com}(\text{crs}, f)$ .
  3. Retrieve  $(C, \mathcal{P}, t, y, \text{com}, \text{time}) \in D$  for the maximum value of  $\text{time}$ . Add  $(C, \mathcal{P}, t, y, \text{com} \cdot \text{com}_0, \text{time}++)$  to  $D$ .
  4. For each  $i \in [n]$ , if  $C$  is corrupt ask  $\mathcal{A}$  for a bit  $b_i^*$ . If  $b_i^* = 1$ , compute  $(\delta_i, \pi_i) \leftarrow \text{KZG.Open}(\text{crs}, f, i)$ . Otherwise set  $(\delta_i, \pi_i) := (\perp, \perp)$ .
  5. If  $P_i$  is corrupt, ask  $\mathcal{A}$  for values  $(\delta'_i, \pi'_i)$  and set  $(\delta_i, \pi_i) = (\delta'_i, \pi'_i)$ . Output  $(\text{sid}, \text{ZeroShare}, P_i, (C, \delta_i, \pi_i))$ .
  6. Finally, output  $(\text{sid}, \text{ZeroSetupDone}, C, (1))$ .
- On input  $(\text{sid}, \text{AuxRecover}, P_i, (C))$  for some client  $C$ , retrieve  $(C, *, *, y, \text{com}, \text{time}) \in D$  for the maximum value of  $\text{time}$  and output  $(\text{sid}, \text{AuxInfo}, P_i, (C, y, \text{com}))$ .

Figure 13: The encrypted secret sharing functionality  $\mathcal{F}_{\text{SS}}$ .

- On input  $(\text{sid}, \text{PKSetup}, P)$ , it proceeds as follows:
  1. Sample  $\text{dk} \xleftarrow{\$} \mathbb{Z}_p$  and set  $\text{ek} := g_2^{\text{dk}}$ .
  2. Delete any existing entries  $(P, *, *, *, *) \in L$  and add  $(P, \text{ek}, \text{dk}, \text{time} := 1, \text{unleaked} := 1)$  to  $L$ .
  3. Output  $(\text{sid}, \text{PKSetupResult}, P, (\text{ek}, \text{dk}))$ .
- On input  $(\text{sid}, \text{PKRecover}, P, (Q))$ , retrieve  $(Q, \text{ek}, *, *, *) \in L$  and output  $(\text{sid}, \text{PKRecoverResult}, P, (Q, \text{ek}))$ .

Figure 14: The public key functionality  $\mathcal{F}_{\text{PK}}$ .

**Parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of prime order  $p$  with generators  $g_1, g_2$ , respectively; a degree- $d$  KZG common reference string  $\text{crs}$ ; hash functions  $H : \{0, 1\}^* \rightarrow \mathbb{G}_1$  and  $\mathcal{H} : \mathbb{G}_2^2 \rightarrow \mathbb{Z}_p$  as defined in 2.7.1 and 5.5, resp.

#### SETUP

Registering a cold storage  $P_i^{\text{cold}}$ : On input  $(\text{sid}, \text{ColdRegister}, P_i^{\text{cold}})$ ,  $P_i^{\text{cold}}$  calls  $\mathcal{F}_{\text{PK}}$  on input  $(\text{sid}, \text{PKSetup}, P_i^{\text{cold}})$  and receives response  $(\text{sid}, \text{PKSetupResult}, P_i^{\text{cold}}, (\text{ek}_i, \text{dk}_i))$ . It stores  $\text{ek}_i, \text{dk}_i$  and outputs  $(\text{sid}, \text{ColdRegistered}, P_i^{\text{cold}}, \text{ek}_i)$ .

Registering a client  $C$ : On input  $(\text{sid}, \text{ClientRegister}, C, (t, \mathcal{I}))$ , where  $\mathcal{I} = \{(P_i^{\text{hot}}, P_i^{\text{cold}})\}_{i \in [n]}$  is a set of institutional entities and  $t \leq n$  a signing threshold:

1.  $C$  calls  $\mathcal{F}_{\text{PK}}$  on input  $(\text{sid}, \text{PKRecover}, C, (P_i^{\text{cold}}))$  for all  $i \in [n]$ . It waits until it receives a response  $(\text{sid}, \text{PKRecoverResult}, C, (P_i^{\text{cold}}, \text{ek}_i))$  for all  $i \in [n]$ .
2.  $C$  calls  $\mathcal{F}_{\text{SS}}$  on input  $(\text{sid}, \text{SSSetup}, C, (t, \{P_i^{\text{hot}}\}_{i \in [n]}, \{\text{ek}_i\}_{i \in [n]}))$ . The latter outputs  $(\text{sid}, \text{SecretShare}, P_i^{\text{hot}}, (C, i, \tilde{x}_i, \pi_i))$  to  $P_i^{\text{hot}} \forall i \in [n]$ . It also outputs  $(\text{sid}, \text{SSSetupDone}, C, (\text{vk}, \{\text{vk}_i\}_{i \in [n]}))$  to  $C$ .
3. Each  $P_i^{\text{hot}}$  stores the tuple  $(C, \tilde{x}_i, \pi_i)$  in a list  $L_i$ . Then it outputs  $(\text{sid}, \text{ClientRegistered}, P_i^{\text{hot}}, (C, b_i = 1))$ .
4. Meanwhile,  $C$  stores the parameters and the values it received from  $\mathcal{F}_{\text{SS}}$  in the tuple  $D = (\text{vk}, \{\text{vk}_i\}_{i \in [n]}, t, \mathcal{I})$ . Finally, it outputs  $(\text{sid}, \text{ClientRegistered}, C, \text{vk}, \{\text{vk}_i\}_{i \in [n]})$ .

#### SIGNING

Threshold signing: On input a signature request  $(\text{sid}, \text{TSign}, P_i^{\text{hot}}, (C, m))$  from a client  $C$ ,

1. If  $P_i^{\text{hot}}$  decides to honor the request, it calls  $\mathcal{F}_{\text{SS}}$  on  $(\text{sid}, \text{AuxRecover}, P_i^{\text{hot}}, (C))$  to get  $\text{vk}$  and sends  $(\text{vk}, m)$  to  $P_i^{\text{cold}}$ . Otherwise, it aborts.
2. If  $P_i^{\text{cold}}$  decides to honor the request, it sends  $\sigma_i^{\text{cold}} := H(m)^r$  to  $P_i^{\text{hot}}$ , where  $r := \mathcal{H}(\text{vk}^{\text{dk}_{i,1}}, \text{vk}^{\text{dk}_{i,2}})$ .
3. Meanwhile,  $P_i^{\text{hot}}$  retrieves  $(C, \tilde{x}_i, *) \in L_i$  and computes  $\sigma_i^{\text{hot}} := H(m)^{\tilde{x}_i}$ .
4. Once it receives  $\sigma_i^{\text{cold}}$ ,  $P_i^{\text{hot}}$  outputs  $(\text{sid}, \text{TSignResult}, P_i^{\text{hot}}, (C, m, \sigma_i := \sigma_i^{\text{hot}} / \sigma_i^{\text{cold}}))$ .

Figure 15: Our BLS hot-cold threshold wallet protocol (setup and threshold signing).

**Parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of prime order  $p$  with generators  $g_1, g_2$ , respectively; a degree- $d$  KZG common reference string  $\text{crs}$ .

#### PROOFS OF REMEMBRANCE

**Cold proof:** A client  $C$  can verify that an institutional cold storage  $P_i^{\text{cold}}$  still retains its key material (namely  $\text{dk}_i$ ). On input  $(\text{sid}, \text{CProof}, C, (P_i^{\text{cold}}))$ ,  $C$  sends a designated proof request message to  $P_i^{\text{cold}}$ . Then:

1.  $P_i^{\text{cold}}$  retrieves its stored  $\text{ek}_i = (\text{ek}_{i,1}, \text{ek}_{i,2})$ ,  $\text{dk}_i = (\text{dk}_{i,1}, \text{dk}_{i,2})$  and computes a non-replayable proof  $\pi_{i,k}^{\text{cold}} \leftarrow \Pi_{\text{DL}}.\text{Prove}(\text{ek}_{i,k}; \text{dk}_{i,k})$  for  $k = 1, 2$ . It sends  $\pi_i^{\text{cold}} := (\pi_{i,1}^{\text{cold}}, \pi_{i,2}^{\text{cold}})$  to  $C$ .
2. To verify,  $C$  calls  $\mathcal{F}_{\text{PK}}$  on input  $(\text{sid}, \text{PKRecover}, C, (P_i^{\text{cold}}))$  and receives  $(\text{sid}, \text{PKRecoverResult}, C, (P_i^{\text{cold}}, \text{ek}_i))$ . It parses  $\text{ek}_i = (\text{ek}_{i,1}, \text{ek}_{i,2})$  and computes  $b_k \leftarrow \Pi_{\text{DL}}.\text{Vrfy}(\text{ek}_{i,k}, \pi_{i,k}^{\text{cold}})$  for  $k = 1, 2$ . Finally it outputs  $(\text{sid}, \text{CProofResult}, C, (P_i^{\text{cold}}, b_1 \wedge b_2))$ .

**Hot proof:** A client  $C$  can also verify that an institutional hot storage  $P_i^{\text{hot}}$  still retains its key material (namely  $\tilde{x}_i$ ). On input  $(\text{sid}, \text{HProof}, C, (P_i^{\text{hot}}))$ ,  $C$  sends a designated proof request message to  $P_i^{\text{hot}}$ . Then:

1.  $P_i^{\text{hot}}$  calls  $\mathcal{F}_{\text{SS}}$  on input  $(\text{sid}, \text{AuxRecover}, P_i^{\text{hot}}, (C))$  and receives  $(\text{sid}, \text{AuxInfo}, P_i^{\text{hot}}, (C, \text{vk}, \text{com}))$ . Then it uses  $\text{com}$  and the stored tuple  $(C, \tilde{x}_i, \pi_i) \in L_i$  to compute  $\pi_i^{\text{hot}} \leftarrow \Pi_{\text{EKS}}.\text{Prove}((\text{crs}, \text{com}, i); (\tilde{x}_i, \pi_i))$ , which it sends to  $C$ .
2. To verify,  $C$  calls  $\mathcal{F}_{\text{SS}}$  on input  $(\text{sid}, \text{AuxRecover}, C, (C))$  and receives  $(\text{sid}, \text{AuxInfo}, C, (C, *, \text{com}))$ . Then it lets  $b \leftarrow \Pi_{\text{EKS}}.\text{Vrfy}((\text{crs}, \text{com}, i), \pi_i^{\text{hot}})$  and outputs  $(\text{sid}, \text{HProofResult}, C, (P_i^{\text{hot}}, b))$ .

#### PROACTIVE REFRESH

**Hot share refresh:** A client  $C$  can trigger a refresh of its hot key shares. On input  $(\text{sid}, \text{ShareRefresh}, C)$ ,  $C$  retrieves its stored wallet parameters  $D = (\text{vk}, *, t, \mathcal{I})$  where  $\mathcal{I} = \{(P_i^{\text{hot}}, P_i^{\text{cold}})\}_{i \in [n]}$ . Then:

1.  $C$  calls  $\mathcal{F}_{\text{SS}}$  on input  $(\text{sid}, \text{ZeroSetup}, C, (t, \{P_i^{\text{hot}}\}_{i \in [n]}))$ .
2.  $\mathcal{F}_{\text{SS}}$  outputs  $(\text{sid}, \text{ZeroShare}, P_i^{\text{hot}}, (C, \delta_i, \zeta_i))$  to  $P_i^{\text{hot}}$  for all  $i \in [n]$ . It also outputs  $(\text{sid}, \text{ZeroSetupDone}, C, (b))$  to  $C$ .
3. Each  $P_i^{\text{hot}}$  checks if  $(\delta_i, \zeta_i) = (\perp, \perp)$ . If so, it sets  $b_i = 0$ ; otherwise, it sets  $b_i = 1$  and updates  $(C, \tilde{x}_i, \pi_i) \in L_i$  to  $(C, \tilde{x}_i + \delta_i, \pi_i \cdot \zeta_i)$ . Then it outputs  $(\text{sid}, \text{ShareRefreshResult}, P_i^{\text{hot}}, (C, b_i))$ .
4. Meanwhile,  $C$  outputs  $(\text{sid}, \text{ShareRefreshResult}, C, (b))$ .

Figure 16: Our BLS hot-cold threshold wallet protocol (proofs of remembrance and proactive refresh).

**Public parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of prime order  $p$  with generators  $g_1, g_2$ , respectively; a degree- $d$  KZG common reference string  $\text{crs}$ ; a hash function  $H : \{0, 1\}^* \rightarrow \mathbb{G}_1$ ; an extractor  $\mathcal{H} : \mathbb{G}_2^2 \rightarrow \mathbb{Z}_p$ .

**Internal variables:**

$L_{\text{cold}} = \{(P^{\text{cold}}, \text{ek}, \text{dk}, \text{leaked}, \text{tampered}, \text{corrupted}, \text{allowc})\}$ , a table with the state of each cold storage's key material.

$D = \{(C, \mathcal{I}, t, y, \text{com})\}$ , a table of registered clients and their metadata.

$L_{\text{hot}} = \{(P^{\text{hot}}, C_j, \tilde{x}, \pi, \text{time}, \text{leaked}, \text{tampered})\}$ , which keeps track of the key material of every hot storage for each of its clients, and whether it has been leaked or tampered with.

$S_{\text{hot}} = \{P^{\text{hot}}, \text{corrupted}, \text{allowc}\}$ , which keeps track of whether each hot party has been corrupted.

### Registration

- On input  $(\text{sid}, \text{ColdRegister}, P_i^{\text{cold}})$ , it proceeds as follows:
  1. Sample  $\text{dk}_i \xleftarrow{\$} \mathbb{Z}_p$  and set  $\text{ek}_i := g_2^{\text{dk}_i}$ .
  2. Delete any existing entries for  $P_i^{\text{cold}}$  in  $L_{\text{cold}}$  and add  $(P_i^{\text{cold}}, \text{ek}_i, \text{dk}_i, \text{leaked} := 0, \text{tampered} := 0, \text{corrupted} := 0, \text{allowc} := 1)$  to  $L_{\text{cold}}$ .
  3. Output  $(\text{sid}, \text{ColdRegistered}, P_i^{\text{cold}}, \text{ek}_i)$ .
- On input  $(\text{sid}, \text{ClientRegister}, C, (t, \mathcal{I}))$ , where  $\mathcal{I} = \{(P_i^{\text{hot}}, P_i^{\text{cold}})\}_{i \in [n]}$  is a set of institutional entities and  $t \leq n$  a signing threshold, it proceeds as follows:
  1. For each  $i \in [n]$ , retrieve  $(P_i^{\text{cold}}, \text{ek}_i, *, *, *, *, *)$  from  $L_{\text{cold}}$ . If a public key for some party is unavailable then output  $y := \perp$ .
  2. Otherwise, sample  $x \xleftarrow{\$} \mathbb{Z}_p \setminus \{0\}$ . Let  $y := g_2^x$ .
  3. Generate  $t$ -out-of- $n$  Shamir Shares of  $x$  as  $x_1, \dots, x_n \in \mathbb{Z}_p$ . Let  $y_i := g_2^{x_i} \forall i \in [n]$ .
  4. Interpolate the degree- $n$  polynomial  $\tilde{f}$  such that  $\tilde{f}(i) = \mathcal{H}(\text{ek}_i^x) + x_i \forall i \in [n]$ . Compute  $\text{com} \leftarrow \text{KZG.Com}(\text{crs}, \tilde{f})$ .
  5. Delete any existing entries  $(C, *, *, *, *, *) \in D$  and add  $(C, \mathcal{I}, t, y, \text{com})$  to  $D$ . Send  $(\text{sid}, \text{ClientRegistered}, C, y, \{y_i\}_{i \in [n]})$  to  $C$ .
  6. For each  $i \in [n]$ :
    - (a) Compute  $(\tilde{x}_i, \pi_i) \leftarrow \text{KZG.Open}(\text{crs}, \tilde{f}, i)$ .
    - (b) Output  $(\text{sid}, \text{ClientRegistered}, P_i^{\text{hot}}, (C, b_i = 1))$ .
    - (c) Once  $\mathcal{A}$  has delivered/allowed delivery of the message, delete any existing entries  $(P_i^{\text{hot}}, C, *, *, *, *, *) \in L_{\text{hot}}$  and add  $(P_i^{\text{hot}}, C, \tilde{x}_i, \pi_i, \text{time} := 0, \text{leaked} := 0, \text{tampered} := 0)$  to  $L_{\text{hot}}$ . Delete any existing entries  $(P_i^{\text{hot}}, \text{corrupted}, \text{allowc}) \in S_{\text{hot}}$  and add  $(P_i^{\text{hot}}, \text{corrupted} := 0, \text{allowc} := 1)$ .

Figure 17: The BLS hot-cold threshold wallet functionality  $\mathcal{F}_{\text{HC}}$  (registration).

## Signing

- On input  $(\text{sid}, \text{TSign}, P_i^{\text{hot}}, (C, m))$ , retrieve  $(C, \mathcal{I}, *, \text{vk}, *) \in D$  and  $(P_i^{\text{hot}}, P_i^{\text{cold}}) \in \mathcal{I}$ . Then:
  1. Get  $(P_i^{\text{cold}}, *, \text{dk}_i, *, \text{tampered}, \text{corrupt}_{\text{cold}}, \text{allowc}) \in L_{\text{cold}}$ . If  $\text{allowc} = 1$ , set it to 0.
    - If  $\text{corrupt}_{\text{cold}} = 1$ , send  $(\text{sid}, \text{CSignRequest}, \mathcal{A}, (P_i^{\text{cold}}, C, m))$  to  $\mathcal{A}$ , wait for response  $b$ , and set  $b_{\text{cold}} := (b \wedge \neg \text{tampered})$ . Otherwise ( $\text{corrupt}_{\text{cold}} = 0$ ), set  $b_{\text{cold}} := \neg \text{tampered}$ .
  2. Retrieve  $(P_i^{\text{hot}}, C, \tilde{x}_i, *, \text{time}, *, \text{tampered}, \text{corrupt}_{\text{hot}}, *) \in L_{\text{hot}}$  for the maximum time.
    - If  $\text{corrupt}_{\text{hot}} = 1$ , send  $(\text{sid}, \text{HSignRequest}, \mathcal{A}, (P_i^{\text{hot}}, C, m))$  to  $\mathcal{A}$ , wait for response  $b$ , and set  $b_{\text{hot}} := (b \wedge \neg \text{tampered})$ . Otherwise, set  $b_{\text{hot}} := \neg \text{tampered}$ .
  3. If  $b_{\text{cold}} \wedge b_{\text{hot}}$ , compute  $\sigma_i^{\text{cold}} := H(m)^{\mathcal{H}(\text{vk}^{\text{dk}_i})}$  and  $\sigma_i^{\text{hot}} := H(m)^{\tilde{x}_i}$ . Let  $\sigma_i := \sigma_i^{\text{hot}} / \sigma_i^{\text{cold}}$ . Output  $(\text{sid}, \text{TSignResult}, P_i^{\text{hot}}, (C, m, \sigma_i))$ .
    - If  $(\text{corrupt}_{\text{cold}} \wedge \neg \text{corrupt}_{\text{hot}})$ , also send  $\sigma_i^{\text{hot}}$  to  $\mathcal{A}$ . If  $(\neg \text{corrupt}_{\text{cold}} \wedge \text{corrupt}_{\text{hot}})$ , send  $\sigma_i^{\text{cold}}$  to  $\mathcal{A}$ .
    - Additionally, for every party  $P_j^{\text{hot}}$  such that  $(P_j^{\text{hot}}, *) \in \mathcal{I}$ , retrieve  $(P_j^{\text{hot}}, *, \text{allowc}) \in S_{\text{hot}}$  and set  $\text{allowc}$  to 0.
  4. If instead  $\neg(b_{\text{cold}} \wedge b_{\text{hot}})$ , output  $(\text{sid}, \text{TSignResult}, P_i^{\text{hot}}, (C, m, \perp))$ .
    - If  $(\text{corrupt}_{\text{cold}} \wedge \neg \text{corrupt}_{\text{hot}})$  or  $(\neg \text{corrupt}_{\text{cold}} \wedge \text{corrupt}_{\text{hot}})$ , also sample  $r \xleftarrow{\$} \mathbb{Z}_p$  and send  $H(m)^r$  to  $\mathcal{A}$ .

## Proofs of Remembrance

- On input  $(\text{sid}, \text{CProof}, P_i^{\text{cold}}, (C))$ , retrieve  $(P_i^{\text{cold}}, \text{ek}_i, \text{dk}_i, *, *, \text{corrupted}, *) \in L_{\text{cold}}$ . If  $\text{corrupted} = 1$ , send  $(\text{sid}, \text{CProofRequest}, \mathcal{A}, (P_i^{\text{cold}}))$  to the adversary, who will send back a bit  $b^*$  to represent whether the query should be responded to honestly. Set  $b := b^* \wedge (\text{ek}_i = g_2^{\text{dk}_i})$  and output  $(\text{sid}, \text{CProofResult}, C, (P_i^{\text{cold}}, b))$ .
- On input  $(\text{sid}, \text{HProof}, C, (P_i^{\text{hot}}))$ , retrieve  $(P_i^{\text{hot}}, C, \tilde{x}_i, \pi_i, *, *, *, \text{corrupted}, *) \in L_{\text{hot}}$  and  $(C, *, *, *, \text{com}) \in D$ . If  $\text{corrupted} = 1$ , send  $(\text{sid}, \text{HProofRequest}, \mathcal{A}, (P_i^{\text{hot}}))$  to the adversary, who will send back a bit  $b^*$ . Set  $b := b^* \wedge \text{KZG.Vrfy}(\text{crs}, \text{com}, i, \tilde{x}_i, \pi_i)$  and output  $(\text{sid}, \text{HProofResult}, C, (P_i^{\text{hot}}, b))$ .

## Proactive Refresh

102

- On input  $(\text{sid}, \text{ShareRefresh}, C)$ , it proceeds as follows:
  1. Output  $\perp$  if a prior share refresh from  $C$  is still pending.<sup>18</sup>
  2. Retrieve  $(C, \mathcal{I}, t, y, \text{com}, \text{time}) \in D$  for the maximum value of  $\text{time}$ .
  3. Generate  $t$ -out-of- $n$  Shamir shares of 0 as  $x_1, \dots, x_n \in \mathbb{Z}_p$  using polynomial  $f$

### Leak

- On input  $(\text{sid}, \text{Leak}, \mathcal{A}, (P_i^{\text{hot}}))$ , for every entry  $(P_i^{\text{hot}}, C_j, \tilde{x}_i, \pi_i, \text{time}, \text{leaked}, *) \in L_{\text{hot}}$ , set **leaked** to 1 and send  $(\text{sid}, \text{LeakResult}, \mathcal{A}, ((P_i^{\text{hot}}, C_j, \tilde{x}_i, \pi_i, \text{time})))$  to  $\mathcal{A}$ .
- On input  $(\text{sid}, \text{Leak}, \mathcal{A}, (P_i^{\text{cold}}))$ , retrieve the entry  $(P_i^{\text{cold}}, \text{ek}_i, \text{dk}_i, \text{leaked}, *, *, *) \in L_{\text{cold}}$ . Set **leaked** to 1 and send  $(\text{sid}, \text{LeakResult}, \mathcal{A}, ((P_i^{\text{cold}}, \text{dk}_i)))$  to  $\mathcal{A}$ .

### Tamper

- On input  $(\text{sid}, \text{Tamper}, \mathcal{A}, (P_i^{\text{hot}}, C, f, g))$ , where  $f, g$  are functions:
  1. Retrieve  $(P_i^{\text{hot}}, C, \tilde{x}_i, \pi_i, \text{time}, \text{leaked}, \text{tampered}) \in L_{\text{hot}}$  for the maximum value of **time**. Let  $\tilde{x}'_i := f(\tilde{x}_i)$  and  $\pi'_i := g(\pi_i)$ .
  2. If  $\tilde{x}'_i, \pi'_i \neq \perp$ , let  $b := 1$  and update the entry to  $(C, P_i^{\text{hot}}, \tilde{x}'_i, \pi'_i, \text{time}, \text{leaked}, \text{tampered} = 1)$ . Otherwise let  $b := 0$ .
  3. Send  $(\text{sid}, \text{TamperDone}, \mathcal{A}, (C, P_i^{\text{hot}}, b))$  to  $\mathcal{A}$ .
- On input  $(\text{sid}, \text{Tamper}, \mathcal{A}, (P_i^{\text{cold}}, f))$ , where  $f$  is a function:
  1. Retrieve  $(P_i^{\text{cold}}, \text{ek}_i, \text{dk}_i, \text{leaked}, \text{tampered}, \text{corrupt}, \text{allowc}) \in L_{\text{cold}}$ . Let  $\text{dk}'_i := f(\text{dk}_i)$ .
  2. If  $\text{dk}'_i \neq \perp$ , let  $b := 1$  and update the entry to  $(P_i^{\text{cold}}, \text{ek}_i, \text{dk}'_i, \text{leaked}, \text{tampered} = 1, \text{corrupt}, \text{allowc})$ . Otherwise let  $b := 0$ .
  3. Send  $(\text{sid}, \text{TamperDone}, \mathcal{A}, (P_i^{\text{cold}}, b))$  to  $\mathcal{A}$ .

### Corrupt

- On input  $(\text{sid}, \text{Corrupt}, \mathcal{A}, (P_i^{\text{hot}}))$ , retrieve  $(P_i^{\text{hot}}, \text{corrupted}, \text{allowc}) \in S_{\text{hot}}$  and check that **allowc** = 1. If so, set **corrupted** to 1. ( $\mathcal{A}$  receives  $P_i^{\text{hot}}$ 's tapes and  $\mathcal{E}$  is notified.)
- On input  $(\text{sid}, \text{Corrupt}, \mathcal{A}, (P_i^{\text{cold}}))$ , retrieve  $(P_i^{\text{cold}}, *, *, *, *, \text{corrupted}, \text{allowc}) \in L_{\text{cold}}$  and check if **allowc** = 1. If so, set **corrupted** to 1. ( $\mathcal{A}$  receives  $P_i^{\text{cold}}$ 's tapes and  $\mathcal{E}$  is notified.)

Figure 19: The BLS hot-cold threshold wallet functionality  $\mathcal{F}_{\text{HC}}$  (adversarial interfaces).

SHARE REFRESH PROOFS ( $\Pi_{\text{Ref}}$ )

**Parameters:** Degree- $d$  KZG common reference string  $\text{crs} = \{g_1, g_1^\tau, \dots, g_1^{\tau^d}, g_2, g_2^\tau\}$ .

Prove $((\text{crs}, \text{ucom}_T, t-1, \{\delta_i\}_{i \in [n]}; z_T(X)) \rightarrow (\{\zeta_{T,i}\}_{i \in [n]}, \pi_z))$ : Given  $\text{crs}$ , a KZG commitment  $\text{ucom}_T$  to update polynomial  $z_T(X)$ , the latter's degree  $t-1$ , and each party's share refresh information  $\delta_i$ , use  $z_T(X)$  to compute the following:

1. For each  $i \in [n]$ , prove that  $\delta_i = z_T(i)$  by computing  $(\delta_i, \zeta_{T,i}) \leftarrow \text{KZG.Open}(\text{crs}, z_T(X), i)$ .
2. Prove that  $z_T(0) = 0$  and  $z_T(X)$  has degree  $t-1 \leq d$  by computing  $(0, \zeta_{T,0}) \leftarrow \text{KZG.Open}(\text{crs}, z_T(X), 0)$  and  $\text{dcom}_T := g_1^{\tau^{d-t+1} \cdot z_t(\tau)}$  using  $\text{crs}$ . Let  $\pi_{\text{ucom}} := (\zeta_{T,0}, \text{dcom}_T)$ .
3. Output  $(\{\zeta_{T,i}\}_{i \in [n]}, \pi_{\text{ucom}})$ .

HVrfy $((\text{crs}, \text{ucom}_T, i, \delta_i), \zeta_{T,i}) \rightarrow \{0, 1\}$ : Given  $\text{crs}$ , a KZG commitment  $\text{ucom}_T$ , party index  $i$ , and share refresh information  $\delta_i$ , output  $\text{KZG.Vrfy}(\text{crs}, \text{ucom}_T, i, \delta_i, \zeta_{T,i})$ .

UCVrfy $((\text{crs}, \text{ucom}_T, t-1), \pi_{\text{ucom}}) \rightarrow \{0, 1\}$ : Given  $\text{crs}$ , a KZG commitment  $\text{ucom}_T$ , and its supposed degree  $t-1$ , verify the proof  $\pi_{\text{ucom}} = (\zeta_{T,0}, \text{dcom}_T)$  by outputting 1 iff the following hold:

$$\begin{aligned} \text{KZG.Vrfy}(\text{crs}, \text{ucom}_T, 0, 0, \zeta_{T,0}) &= 1 \\ e(\text{dcom}_T, g_2) &= e(\text{ucom}_T, g_2^{d-t+1}) \end{aligned}$$

Figure 20: The proof system  $\Pi_{\text{Ref}}$  used to prove correctness of the every hot party's share refresh information  $\delta_i$  and the commitment update  $\text{ucom}_t$ . Each hot party verifies its own update information using  $\text{HVrfy}$ , and the correctness of  $\text{ucom}$  is verified separately via  $\text{UCVrfy}$ .

**Public parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of order  $p$  with generators  $g_1, g_2$ , respectively.

- On input  $(\text{sid}, \text{Setup}, C, (\text{vk}, t, \text{com}))$ , delete any existing entries  $(C, *, *, *, *) \in D$  and  $(C, *, *) \in U$ . Add  $(C, \text{vk}, t, \text{com}, \text{time} := 0)$  to  $D$  and output  $(\text{sid}, \text{SetupResult}, C, (1))$ .
- On input  $(\text{sid}, \text{ComUpdate}, C, (\text{ucom}, \pi_{\text{ucom}}))$ :
  1. Retrieve  $(C, \text{vk}, t, \text{com}, \text{time}) \in D$  for the maximum value of **time**.
  2. If  $\Pi_{\text{Ref}}.\text{UCVrfy}((\text{crs}, \text{ucom}, t), \pi_{\text{ucom}}) = 1$ , set  $b := 1$  and add  $(C, \text{vk}, t, \text{com} \cdot \text{ucom}, \text{time}++)$  to  $D$  and  $(C, \text{ucom}, \text{time}++)$  to  $U$ . Otherwise set  $b := 0$ .
  3. Output  $(\text{sid}, \text{ComUpdateResult}, C, (b))$ .
- On input  $(\text{sid}, \text{ClientInfoRecover}, P, (C))$ , retrieve  $(C, \text{vk}, *, \text{com}, \text{time}) \in D$  for the maximum value of **time** and output  $(\text{sid}, \text{ClientInfo}, P, (C, \text{vk}, \text{com}))$ .
- On input  $(\text{sid}, \text{UComRecover}, P, (C))$ , retrieve  $(C, \text{ucom}, \text{time}) \in U$  for the maximum value of **time** and output  $(\text{sid}, \text{UCom}, P, (C, \text{ucom}))$ .

Figure 21: **The Programmable Bulletin-Board Functionality  $\mathcal{F}_{\text{BB}}$**

ENCRYPTED SECRET SHARING PROTOCOL

**Public parameters:** Groups  $\mathbb{G}_1, \mathbb{G}_2$  of prime order  $p$  with generators  $g_1, g_2$ , respectively; a degree- $d$  KZG common reference string  $\text{crs}$ .

Setup: On input  $(\text{sid}, \text{SSSetup}, C, (t, \mathcal{P}, \{\text{ek}_i\}_{i \in [n]}))$ , where  $t, n \in \mathbb{N}$  s.t.  $n = |\mathcal{P}|$  and  $t \leq n \leq d$ ,  $\mathcal{P} = \{P_1 \dots P_n\}$  a set of parties, and  $\{\text{ek}_i\}_{i \in [n]}$  a set of public (encryption) keys ( $\forall i \in [n], \text{ek}_i \in \mathbb{G}_2$ ),  $C$  proceeds as follows:

1. Sample  $x \xleftarrow{\$} \mathbb{Z}_p \setminus \{0\}$ . Let  $y := g_2^x$ .
2. Generate  $t$ -out-of- $n$  Shamir Shares of  $x$  as  $x_1, \dots, x_n \in \mathbb{Z}_p$ . Let  $y_i := g_2^{x_i} \forall i \in [n]$ .
3. Interpolate the degree- $n$  polynomial  $\tilde{f}$  such that  $\tilde{f}(i) = \mathcal{H}(\text{ek}_i^x) + x_i \forall i \in [n]$ . Compute  $\text{com} \leftarrow \text{KZG.Com}(\text{crs}, \tilde{f})$  and send  $(\text{sid}, \text{Setup}, C, (y, t, n, \text{com}))$  to  $\mathcal{F}_{\text{BB}}$ .
4. Delete any existing entries  $(C, *, *) \in D$  and add  $(C, \mathcal{P}, t)$  to  $D$ .
5. For each  $i \in [n]$ , compute  $(\tilde{x}_i, \pi_i) \leftarrow \text{KZG.Open}(\text{crs}, \tilde{f}, i)$  and output  $(\text{sid}, \text{SecretShare}, P_i, (C, i, \tilde{x}_i, \pi_i))$ .
6. Finally, output  $(\text{sid}, \text{SSSetupDone}, C, (y, \{y_i\}_{i \in [n]}))$ .

Generating share refreshes: On input  $(\text{sid}, \text{ZeroSetup}, C, (t, \mathcal{P}))$ , where  $t, n \in \mathbb{N}$  s.t.  $n = |\mathcal{P}|$  and  $t \leq n \leq d$ , and  $\mathcal{P} = \{P_1 \dots P_n\}$  a set of parties,  $C$  will proceed as follows:

1. Generate  $t$ -out-of- $n$  Shamir Shares of 0 as  $x_1, \dots, x_n \in \mathbb{Z}_p$ ; let  $f$  be the polynomial used.
2. Compute  $\text{com}_0 \leftarrow \text{KZG.Com}(\text{crs}, f)$  and  $(\{\zeta_i\}_{i \in [n]}, \pi_z) \leftarrow \Pi_{\text{Ref}}.\text{Prove}((\text{crs}, \text{com}_0, t - 1, \{x_i\}_{i \in [n]}); f(X))$ . Send  $(\text{sid}, \text{ComUpdate}, C, (\text{com}_0, \pi_z))$  to  $\mathcal{F}_{\text{BB}}$ , which returns  $(\text{sid}, \text{ComUpdateResult}, C, (b))$ .
3. Send  $(x_i, \zeta_i)$  to  $P_i$  for all  $i \in [n]$ , then output  $(\text{sid}, \text{ZeroSetupDone}, C, (b))$ .
4. Each party  $P_i$  for  $i \in [n]$  will send  $(\text{sid}, \text{UComRecover}, P_i, (C))$  to  $\mathcal{F}_{\text{BB}}$  and receive  $(\text{sid}, \text{UCom}, P_i, (C, \text{ucom}))$  in return. Check that  $\Pi_{\text{Ref}}.\text{HVerfy}((\text{crs}, \text{ucom}, i, x_i), \zeta_i) = 1$ . If not, set  $x_i, \zeta_i = \perp$ . Output  $(\text{sid}, \text{ZeroShare}, P_i, (C, x_i, \zeta_i))$ .

Providing auxiliary information: On input  $(\text{sid}, \text{AuxRecover}, P, (C))$  for some client  $C$ ,  $P$  sends  $(\text{sid}, \text{ClientInfoRecover}, C)$  to  $\mathcal{F}_{\text{BB}}$  to get  $(\text{vk}, \text{com})$ . It outputs  $(\text{sid}, \text{AuxInfo}, P, (C, \text{vk}, \text{com}))$ .
